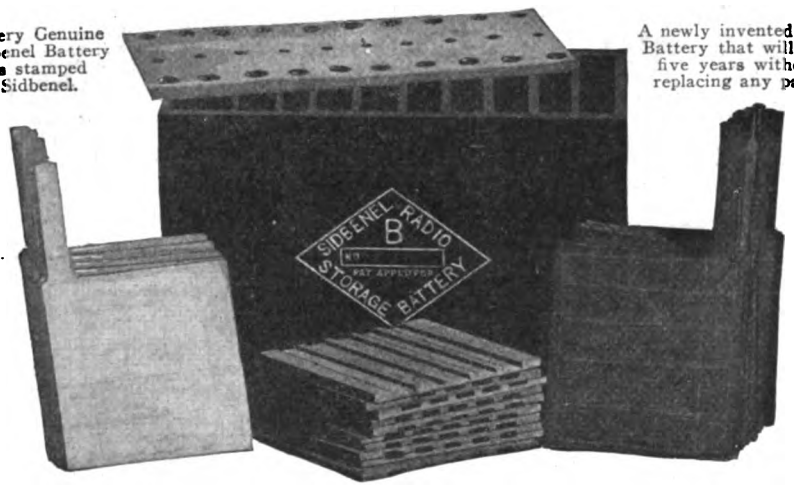
[illegible] TRANSFORMERS
A. F. 3 to 1, $2.50

THIS "B" BATTERY WILL LAST 5 YEARS

Every Genuine Sidbenel Battery is stamped Sidbenel.

A newly invented "B" Battery that will last five years without replacing any part.



OVER 10,000 SIDBENEL STORAGE "B" BATTERIES have been sold in the last few months. This is conclusive proof that it is the desired radio "B" battery. It will outlast any other type of battery and possesses every known improvement. The patented features include the composition and treatment of the plates, which is entirely different from any other battery. The plates are especially treated with a newly discovered chemical that enables you to draw as low as ten milliamperes without causing the electrical reaction which is a constant internal discharging of the batteries when insufficient current is being drawn from the plates. This self-discharging of the plates, causing the cricking and howling heard in various degrees of loudness in the receivers when using other batteries. It has been proven by actual test that SIDBENEL STORAGE "B" BATTERIES is the only battery that eliminates this electrical reaction.

Each unit is constructed in one piece of hard rubber moulded into ten compartments. Each complete unit is 2½ in. x 3 in. x 4½ in. Note the rigid and substantial construction as shown in the illustration. A special heavy ridge runs through the bottom making it practically unbreakable and enabling us to guarantee it against leakage. The cover is easily detachable allowing you to give the battery a thorough inspection without removing the plates.

A single charge lasts approximately six months. It is recharged in a few hours from A.C. or D.C. lamp socket or farm lighting generator to its original full capacity.

The enormous amount of energy enables the vacuum tube to make weak signals exceptionally loud and clear. You will notice the wonderful improvement in reception on your first trial.

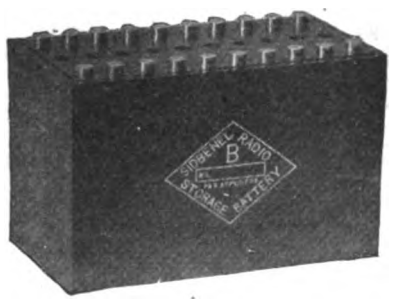
The units are bottom heavy so that they will not turn over. All the features of the SIDBENEL BATTERY are covered by our patents.

Complete battery weighs only 2¼ lbs.

There are no "just as good" batteries. Our trade mark is on every unit.

The battery is shipped to you assembled, or partly assembled. When buying unassembled all you have to do is connect the plates together. This takes less than ten minutes. Any boy can do it. Illustrations and plain instructions with each battery. The plates are already formed and charged before shipping.

Each unit can be tapped at any desired voltage. Full capacity is 22½ volts. For higher voltage simply connect additional units in series.



One single unit—23 volts—variable from 2 volts up.....$4.25

Two single units	**$8.10**	**Five single units**	**$18.50**
Three single units	**11.75**	**Six single units**	**22.25**
Four single units	**15.25**	**Seven single units**	**25.75**

ASSEMBLED PER UNIT $4.65

STANDARD *Sidbenel* RADIO "A"

Every Sidbenel A Battery is made from the very finest materials that can be obtained. Sidbenel A Batteries are the products of a firm long established whose motto is "We must build the best." We have never wavered from our policy to ignore quantity production and to preserve quality. Our principle and business methods are as sound and conscientiously honest as the Sidbenel Battery itself.

"You can always depend on Sidbenel—absolutely."

RADIO PERFECTION

BESTONE
Spring Grip Telephone Plug

The Bestone Plug is an entirely radical departure in design and construction, giving superior results.

A simple pressure of the buttons instantly connects or disconnects the receivers. It is not necessary to disassemble the Bestone Spring Grip Plug for any reason. Just insert the cord tips—no more work, worry, or possibility of a poor connection.

Eliminates the use of several plugs—enables you to use from one to three sets of telephone receivers, or to change from head phones to loud speaker, without disconnecting. List **$1.25**

is attained only by the use of mechanically and scientifically perfect parts.

Now, more than ever, when the market is flooded with inferior goods, one cannot be too careful in the selection of standard, trade-marked articles, and in purchasing from a reliable source.

It is our aim to supply the highest standard radio specialties, thus insuring perfect results and satisfaction.

Every article we sell is unconditionally guaranteed both by the manufacturer and this organization.

MAHOGANY FINISH

Makers of the famous Dictograph Radio Headsets—the Best Headsets in the world at **any** Price. First choice of experts. $8 at your dealers.

The New Radio Loud Speaker

With the Adjustable Air Cap

The Dictogrand overcomes the defects common to all other loud speakers. By simply turning a dial on the base, all harsh or unwelcome sounds are quickly hushed and the purity of the original voice or instrument duplicated with marvelous clearness.

How It Does It

This result is secured by varying the air gap between the diaphragm and the poles of the magnet, thus controlling the pull of the magnet on the diaphragm and permitting tuning into complete harmony under all conditions of reception.

Only $28.50

This valuable improvement adds nothing to what you pay. The Dictogrand costs you no more—even less—than other standard makes which lack this feature. Like all Dictograph products the Dictogrand is guaranteed for one year against all electrical and mechanical defects.

No Extra Batteries Required—Just Plug in and Listen

Get a Demonstration

If your dealer already has the Dictogrand in stock, ask him to let you hear it. Nothing will so quickly convince you how superior it really is to any loud speaker you have ever heard. The instantt demand for the Dictogrand has made it impossible, so far, for us to get full distribution. So if your dealer has not yet received his stock, send to us direct.

DEALERS: Order through your jobber, or write direct for names of authorized distributors.

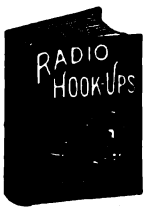
IF YOU ARE INTERESTED IN RADIO YOU NEED THESE BOOKS

RADIO BOOKS THAT HELP YOU

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Radio Hook-Ups

By M. B. SLEEPER

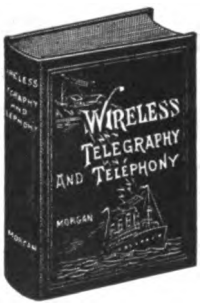
A book that gives you not only clear diagrams for all kinds of telephone and telegraph receiving and transmitting sets, but simple descriptions of each circuit shown and spaces for notes of results obtained.

PRICE 75c.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

There is a peculiar fascination about receiving radio messages from the high-power stations of England, France, Germany, Russia and Italy, as well as those located in the Pacific Ocean and the Oriental countries. Several types of simple receiving sets for this purpose are described, with detectors and amplifiers to accompany them. Suggestions are also given for operating relays and reproducing the signals on a phonograph. Schedules of operating time for high-powered stations are given. In addition, there is some valuable data on home-made wavemeters for testing and experimenting .....PRICE 75c.



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50

Design Data for Radio Transmitters and Receivers

By M. B. SLEEPER

The only book that gives tables and data for designing, receiving and transmitting apparatus so that you need no knowledge of mathematics. It's the first book a beginner buys after he has learned the use of his phone receiver.....PRICE 75c.

Construction of Radiophone and Telegraph Receivers for Beginners

By M. B. SLEEPER

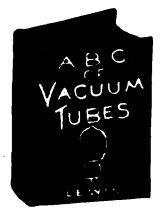
The man who wants to feel the real thrill of accomplishment, and who is not satisfied in the merely making use of what others have done for him, builds his own radio apparatus. Radio men can follow the data in "Radio Phone and Telegraph Receivers" with full confidence, because each piece of apparatus described was first made, tested and found efficient before the final design was accepted. Special receivers, both crystal and audion, are shown in detail. Regenerative circuits as well as audio and radio frequency amplifiers are described with clear photos, diagrams, and working drawings prepared especially for the novice and the man who wants to receive the radio telephone broadcast. A special feature is the phonograph type radio set and the loud speaker. Fully illustrated.....PRICE 75c.

The Radio Experimenter's Handbook

By M. B. SLEEPER

Throughout the preparation of this book, one purpose was kept in mind—Answer the Practical Questions of the "Novice," of the "Beginner," and the more advanced "Student." This book will help in the selection or construction of simple apparatus for the transmission and reception of radio telegraph and telephone signals. In the chapters on radio receivers the simplest crystal, the simple audion, and the regenerative types are described in quite some detail. The question of antennas, both for transmitting and receiving, are taken up. A good many helpful suggestions are given which will be of considerable aid to the experimenter. 16 chapters. Fully illustrated.

PRICE $1.00



The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

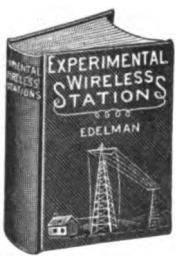
Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

How to Make Commercial Type Radio Apparatus

By M. B. SLEEPER

This book describes in detail many commercial types of spark and vacuum tube telephone transmitting and telegraph and phone receiving equipment of all kinds. The experimenter will be able to get a world of ideas for the design and construction of his next piece of radio equipment from the very clear descriptions and the 98 clearly illustrated figures.....PRICE 75c.



Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations.....PRICE $2.00

FADA "ONE-SIXTY" RECEIVERS

Using the Famous NEUTRODYNE Circuit

A four-tube reflex receiver incorporating two stages of tuned radio frequency amplification, vacuum tube detector, and two stages of audio frequency amplification. The **Neutrodyne** circuit neutralizes the capacity coupling of the circuit, allowing very efficient radio frequency amplification. From New York City using only a fifty foot indoor antenna every class B broadcasting station in the United States is heard with loud speaker intensity. Concerts from KF1, Los Angeles, WOA1, San Antonio, Texas, and PWX, Habana, Cuba, are enjoyed most every night.

Truly—here is the ideal receiver.

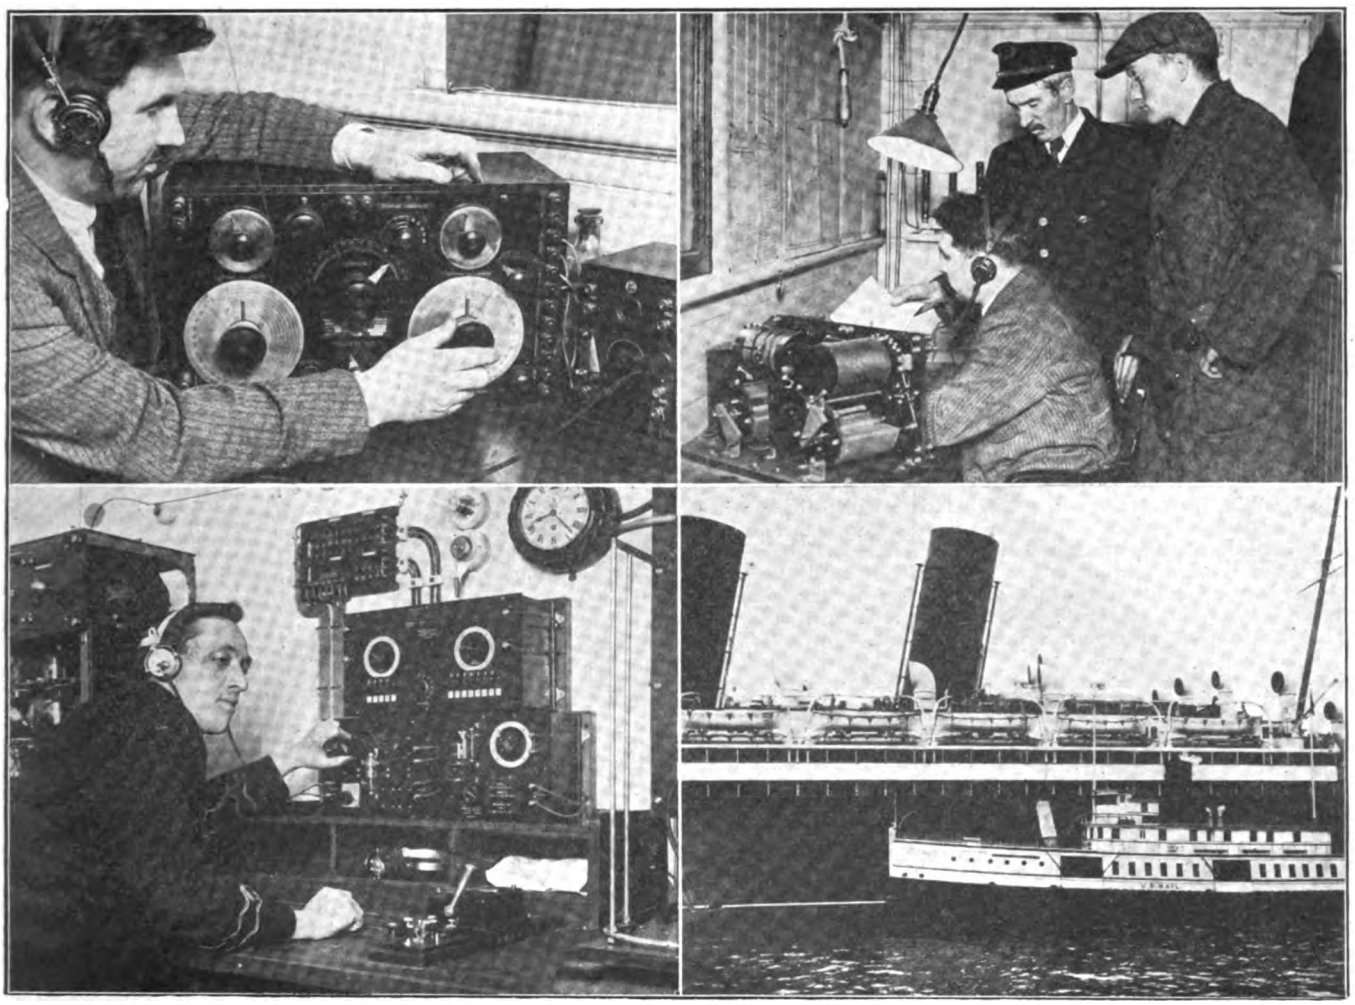
U. S. S. "President" First Radio Equipped Mail Boat in Service

By John Kent

The illustration below shows Operator M. G. Carter, with the new navy type regenerative receiver used on board the mail boat "President." It has a range of from 250 to 3,500 meters.

Captain A. Hillary, master, receiving information from the S.S. "Majestic" by means of radio. This picture also illustrates the interior of the receiver shown complete on the left.



(C. Kadel and Herbert)

The above illustration shows the powerful transmitter and receiver on board the S.S. "Majestic." First Operator F. Garwood informing the mail boat just how much mail to expect.

This picture shows mail being transferred from the S.S. "Majestic," one of the palaces of the sea, to the U. S. mail boat "President," one of the "mail carriers of the ocean lanes."

ALONG with the increase in imports and exports, there, of course, comes an increase in the amount of foreign mail arriving in this country. It is the custom of the mail boats to meet the large steamers down New York Bay to collect the mail so that everything will be facilitated and speed made possible.

The latest improvement to increase the efficiency in the handling of the mail, was equipping the U. S. Mail Boat "President" with an up-to-the-minute radio receiving set and powerful transmitter. Before the boat was equipped it was impossible to determine accurately just how many bags of mail the incoming liners had. But now, by means of radio, the mail boat is always in direct communication with the incoming boats and therefore can be informed how much mail is aboard.

This information is very valuable to the service, for otherwise the officials would not know how many men to send out to meet the incoming liner to help handle the ship's mail.

The radio installation made on the "President" is the latest type of apparatus used by the government. Competent and experienced operators are being trained to meet the demand when all the boats in the service are thus equipped, which will be in the near future.

Letters of Congratulation to Radio World on Its Anniversary

FROM HON. THEODORE ROOSEVELT, ASSISTANT SECRETARY OF THE NAVY

I am pleased to learn that your publication, RADIO WORLD, has been favorably received, and trust that it will continue to meet with success.

The Navy Department is keenly interested in all movements to further the progress of radio, whether by education, by research, or by design, as it is firmly believed that the science of radio communication is an invaluable adjunct to national industrial progress as well as to the national defense.

FROM DR. A. E. KENNELLY, PROFESSOR OF ELECTRICAL ENGINEERING, MASSACHUSETTS INSTITUTE OF TECHNOLOGY

I am glad to hear that RADIO WORLD has come through its first year of public service in good health and doing well.

The subject of world communication calls for our best abilities in radio communication in addition to all that can be furnished by wire and cable. There is something marvelously fascinating about radio and its work that the public is always ready to listen to, if suitably presented, and it seems to me RADIO WORLD is undertaking a share of that task with satisfaction and success. I wish it continued and yet increasing success in the future.

FROM DR. LEE DE FOREST, WIRELESS PIONEER

I congratulate RADIO WORLD on the success which it has attained. It has done more than its share in arousing and keeping alive the ever-increasing popular interest in this magnificent new art of radio broadcast.

I wish RADIO WORLD and its staff continued and renewed success.

FROM DR. FRANK CRANE, EDITOR "CURRENT OPINION"

Radio has literally opened up a new world, and the possibilities that lie within it are staggering to the imagination. Every intelligent person must be interested in the progress made in this important field.

FROM JACK BINNS, RADIO EDITOR, "NEW YORK TRIBUNE"

When public interest was first attracted to radio there were many pessimists who said: "It is just a passing craze and will soon die out like other crazes have." These pessimists have already been refuted and radio has shown itself to be a public utility of very great importance, besides being a very interesting and entertaining means of amusement. The history of RADIO WORLD clearly proves this statement.

FROM GENERAL J. G. HARBORD, PRESIDENT RADIO CORPORATION OF AMERICA

It is a pleasure to pass on to you and to readers of RADIO WORLD a few remarks concerning some of my views on radio broadcasting.

Broadcasting appeals to the imagination as no other invention of the times. Its possibilities are beyond human comprehension. It is the romance and the inspiration of the world's splendid prime. No permanent record of the last act of "Il Trovatore," as given by the Chicago Grand Opera Company and actually heard in New York—no record, although equally perfect in its reproduction, is equal or comparable to hearing it by radio at the second it was rendered. One is history, the other action, timely and instantaneous.

The value of broadcasting to any individual or community will be in proportion to the difficulty of getting the same thing by any other means. Next to saving life at sea, radio's greatest service will be through the intelligent broadcasting of programs that will not only satisfy the desires of the average listener from an entertainment point of view, but will also be an interpreter of public tastes and opinions and of practical value in the furnishing of news, market reports, weather reports, time signals and religious services to people who live in remote districts.

Of one thing we are certain: Broadcasting is here to stay. But who is going to do it in the future and who is going to pay for it is a question which I cannot answer. But it seems to me that it must be organized and administered as a national service with the ideal, "the greatest good to the greatest number" as the watchword. If such a situation is brought about, it will, no doubt, be possible to devise some means to obtain compensation for the service either from manufacturers and distributors of radio apparatus, suitable contribution from listeners, or from the public-spirited endowment of a Carnegie or Rockefeller.

FROM REAR ADMIRAL W. A. MOFFETT, U. S. N., CHIEF BUREAU OF AERONAUTICS, UNITED STATES NAVY

My congratulations upon the success which RADIO WORLD has met, and I am truly pleased at this.

To naval aviation radio is one of our most important instruments for successful operation. Its use in communication between aircraft in flight, between aircraft and ship and between aircraft and shore has tremendously enhanced the value of aircraft in warfare. The development of aircraft radio and the development of the use of aircraft in fleet operations go hand in hand.

I wish RADIO WORLD every possible prosperity.

Radio on the Pacific

ALTHOUGH there are thirteen cables on the Atlantic, one cable only connects the United States with the Far East—that of the Pacific Commercial Company.

This cable has a limited capacity and is out of commission frequently for months at a time, due to the coral formation on the ocean's bottom between Guam and Manila. There has been some talk of another Pacific cable, but the physical conditions of the bottom are such that the laying of a second cable is a very expensive proposition. With the increasing facilities offered by radio, it is doubtful if the necessary money could be subscribed to finance such an undertaking, Naval experts believe.

The Navy has several radio circuits across the Pacific, the giant of which, both in length and volume of traffic, is that from San Francisco to Cavite in the Philippines. About one-third of all traffic goes clear across the Pacific and the other two-thirds is relayed at Honolulu or Guam, or both. There is a half-hourly schedule between San Francisco and Honolulu so that this service is practically continuous. Commercial traffic cannot be accepted at the San Francisco Naval station for Honolulu, although it is handled by points beyond Honolulu. Press traffic only is carried between San Francisco and Honolulu. Across the Pacific, Naval stations are located at Honolulu, Guam and Cavite and reaching to the southward, there is one at Tutuila, in the Samoan Islands. From Guam to Japan, messages are transmitted by cable, although there is no reason why radio could not be used if Japan would open its stations to such messages.

In Alaska, the principal Naval radio stations are at Sitka, Ketchikan, Seward, Kodiak, Cordova, Dutch Harbor and St. Paul. As the Alaska cable is often out of commission, this chain is frequently called upon to accept commercial messages for the northwest. The Naval radio station at Cavite is in communication with French Indo-China and the Dutch East Indies, and a commercial traffic agreement with the respective administrations exists. Northward from Cavite are the circuits to Peking and Shanghai.

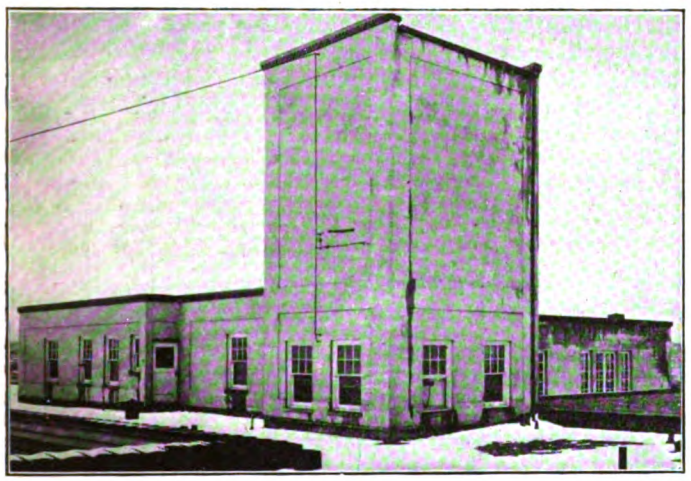
Newark Apartment Building First to Give Tenants Complete Radio Service

NEWARK, N. J., claims the distinction of being the first city in which apartment house owners give their tenants complete radio service.

This service, which in truth might be said to be the last word in modern improvements, is accomplished by means of an adaptation of the Western Electric Company's public address system installed in the pent house atop the Ritz Apartments at 299 Clinton avenue, Newark, N. J.

In any of the 72 suites a member of a family, by merely slipping on a headset and inserting a convenient plug, can comfortably sit in his or her home and listen to the country's best radio programs.

F. B. Kopff, the superintendent of the building, says the popularity of this innovation in apartment house service is evidenced by the fact that but comparatively little elevator service is required in the evenings; the greater number of the Ritz tenants prefer to stay in and listen in to radio programs.



(C. Western Electric Co.)
Pent house and radio room atop the Ritz Apartments, Newark, N. J., the first radio equipped apartment house on record.

The operator up in the radio room on the Ritz roof must needs combine diplomacy with ability when he selects and picks up from the air a program that will suit the preferences of all the people in the 72 apartments. But thus far he has been so successful in his selection that even a loud speaker could not make the complaints audible, for there have been none. However, should such a contingency ever occur, it will be readily taken care of by installing an additional radio receiving set.

The equipment now used gives adequate service. It consists of a radio receiving set and a high-power amplifier. There are four vacuum tubes in the receiver which provide a means of detection, two stages of radio frequency and a single stage of audio frenquency amplification. The complete set can be operated on dry batteries.

Because of the set's sensitiveness and selectivity every city in the country which has a 500-watt broadcasting station has been heard by the families living in the Ritz Apartments.

By means of a specially designed input coil, the radio receiver is connected to a Western Electric amplifier. Power type tubes provide three stages of audio frequency amplification, the last stage being push and pull. Incoming radio signals detected by the radio receiver are amplified and thence wired to all of the 72 apartments, each of which is equipped with a Western Electric headset of high impedance type and with a special receptacle. The telephone jacks used in these receptacles are so arranged that no matter whether a few or all 72 headsets be used, the quality and volume will be in no wise impaired.

The possibility that apartment houses which provide

(C. Western Electric Co.
David H. O'Brien, of the Western Electric Co., and William McNeery (The Man-in-the-Moon) in the radio room of the Ritz Apartments.

radio service may become as tumultuous as the Tower of Babel is easily averted. By using headsets rather than loud speaking projectors, there can be no "bedlam," and each lessee is given clear reception.

Superintendent Kopff believes in the practical application of the old adage: "All work and no play makes

(C. Western Electric Co.
Master Morty Gross listening to the radio which is amplified in each apartment in this new radio equipped apartment.

Jack a dull boy." He finds that the workers in the big boiler room of the Ritz perform their tasks with much more zest after intermissions or "recesses for radio."

The Ultimate Coupler—How to Make It

By Arthur S. Gordon

YOU will enjoy making the improved variocoupler described and illustrated in this article. It represents the very peak of variocoupler construction and embodies the theories which are found in the best instruments on the market. It is designed especially for concert work, but a bank-wound loading coil connected in series with the primary and the antenna will transform it into the finest multi-wave tuner you ever

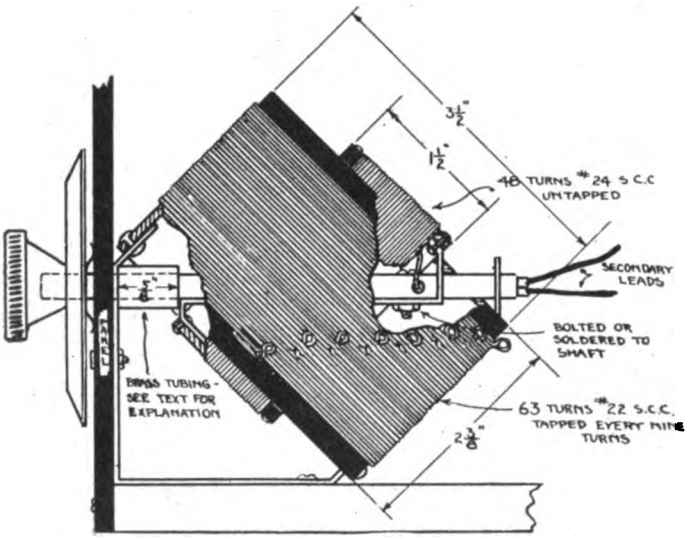

Fig. 1. Constructional details of the coupler described in the accompanying text. The secondary, or rotor, is fashioned to fit on a Z-shaped piece of metal allowing 180° variation, which is impossible with the present-day type.

saw. It was originally built for use in single or double-circuit regenerative receivers, but it may be used successfully in single or multitube reflex circuits, or in the reflex hook-up which employs a crystal as a detector.

The variocoupler has always been a favorite tuning device for both short and long wave reception. Usually there are two coils of wire in a variocoupler, one called the primary and the other called the secondary. The

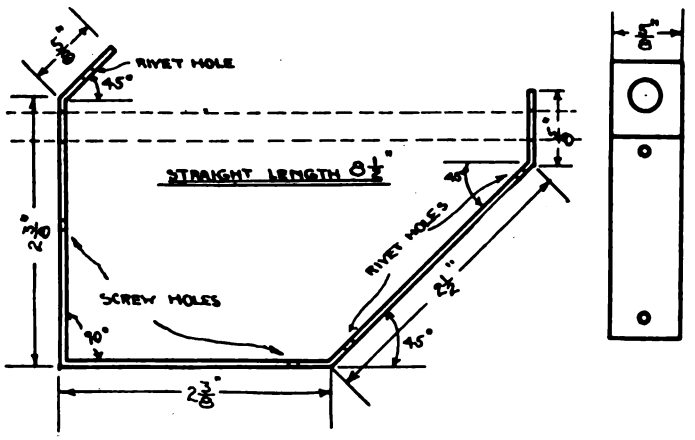

Fig. 2. The standard for the stationary coil is bent into shape from a strip of fairly heavy brass. It should be done very accurately if success is to be expected.

primary coil is stationary, is generally wound upon a tubular form, and is connected to the aerial-ground circuit as the main inductance. It carries the original current. The secondary coil is movable, is wound either on a tube or a ball, and is so placed with reference to the primary coil that a current is induced from one winding to the other. The amount of current so induced—or self-generated by the secondary on account of its nearness to the primary coil—is varied by moving the secondary in or out of the primary, as in a loose coupler, or by revolving the secondary in such a manner as to change the angle of its turns from zero to ninety degrees. This variable relationship of the two coils is known as coupling.

The particular instrument described here has the advantage of extreme coupling combined with the greatest amount of inductance. The movable coil is always in the center of the stationary coil, in which position it works best. The turns of the secondary are not divided on both sides of a spindle hole, as with most instruments. Above all, the construction of this Rolls Royce among couplers has been simplified so as to be within the mechanical skill of the average amateur. A glance at Fig. 1, which is an assembly view of the completed instrument, may disprove the preceding statement, but when it is considered that there is not a detail omitted from this assembly view, the preconception of difficulty disappears. In other words, Fig. 1 could be published without any text or detailed sketches, and a fair proportion of fans among us could build the instrument intact. However, a full explanation of how

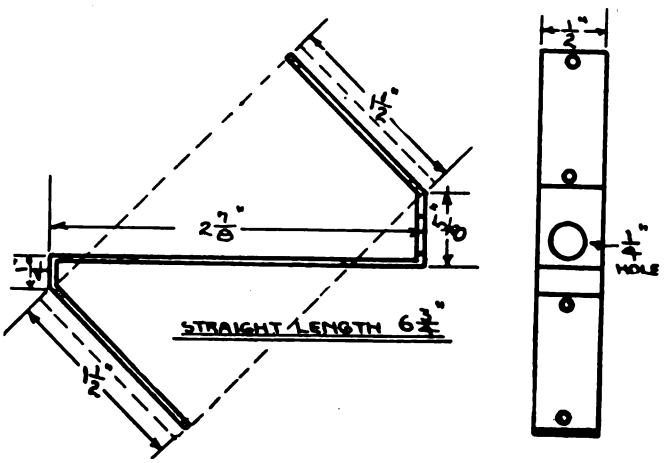

Fig. 3. The standard for the rotor which is bent out of heavy brass strip, and makes possible the 180° coupling.

to wind the coils, how to mount them and how to assemble them is given in the succeeding paragraphs.

The primary of this modern variocoupler is a stationary coil mounted at an angle of 45 degrees on a brass standard. This standard is fastened either to the back of the panel, to the baseboard, or to both, as shown in Fig. 1. The tube upon which the coil is wound may be either bakelite or cardboard. Bakelite is preferred on account of its higher insulating qualities and rigidity. The diameter is 3½ inches and the length 2⅜ inches. Sixty-three turns of No. 22 S. C. C. copper wire are about right for concert reception, with enough spare inductance to climb to 600 meters if desired.

There are no single taps on this coupler, eight turns being the closest to which the primary coil can be adjusted. Experience has demonstrated that while single taps on the primary of the coupler are sometimes needed, the majority of receivers work just as well without them. In other words, single wire taps are nice, but not exactly necessary. Close tuning is

(Continued on next page)

Digitized by Google

(*Continued from preceding page*)

done by coupling, and by use of the variable condenser. Should any one care to include single taps, however, the first nine turns are brought in succession to a switch, then every nine turns thereafter. Otherwise bring out a tap every nine turns, making seven in all.

Begin the winding about ⅜-inch from the edge of the tube. Twist the beginning of the wire into a loop, wrap the twisted portion with a single layer of tape or adhesive plaster, and bind the first turn to the coil by passing the succeeding turns over the ends of the tape. See Sketch 1 of Fig. 5. This idea originated with an English amateur who passes it on for approval.

The winding, however, is not started until the standard for the tube is made and riveted in place. This standard serves the triple purpose of holding the coil at its proper angle, providing the rotor shaft with bearings and giving the instrument a base on which to stand. A strip of fairly heavy brass ⅝-inch wide and 8½ inches long is bent carefully into the shape shown in Fig. 2. Three rivet holes are drilled as indicated, being placed so that the rivets will be on the outer

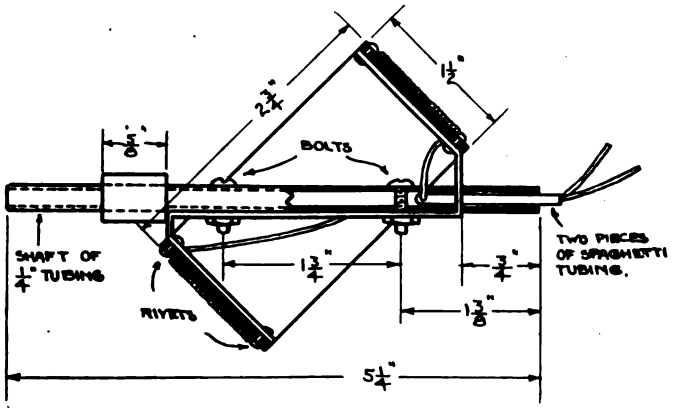

Fig. 4. Diagram showing the manner of fastening the coil on the standard. The shaft, which is hollow, is then bolted or soldered to the Z-shaped piece. This makes a solid looking and working rotor for the Ultimate Coupler.

margin of the coil and not so far toward the center as to interfere with winding. The screw holes are also drilled as shown.

In placing the two ¼-inch holes for the shaft, take pains to drill them so that the shaft is level. A slight inaccuracy here will make no great difference, however, as the inner coil is designed so as to allow a little leeway. In the interests of balanced operation, it is urged that more than usual care be taken.

For a detail of the rotor shaft, see Fig. 4. There it is shown to be, not a rod, but a brass or copper tube 5¼ inches long by ¼-inch outside diameter. It is drilled in four places. Two bolt holes are provided for small and thin bolts which are used to fasten the brass form on which the secondary coil is riveted, to the shaft. The details of this form, shaped like a letter Z, are given in Fig. 3. A strip of brass or copper 6¾ inches long by ½-inch wide is required. It is riveted to the inside of the secondary coils by four rivets, holes for which must be drilled beforehand. This Z shaped strip of brass is drilled with bolt holes to correspond with those on the shaft, and it is also drilled with a ¼-inch hole so that it will slip over the end of the shaft preliminary to bolting.

Of such a size as to slip over the rotor spindle is a short piece of larger brass tubing, ⅝-inch long. It is shown in Fig. 1 as a space washer between the upright leg of the primary standard and the forward end of the secondary form. This washer, or sleeve, plays a very important part in the mechanical—not the electrical—operation of the coupler. It cannot be dispensed with unless there is a shoulder on the rotor shaft so placed as to prevent the entire secondary element from moving forward. A movement in the other direction is prevented by the dial on the outside of the panel, with a spring placed between them to keep a necessary and convenient tension.

The secondary of this coupler is wound on a tube,

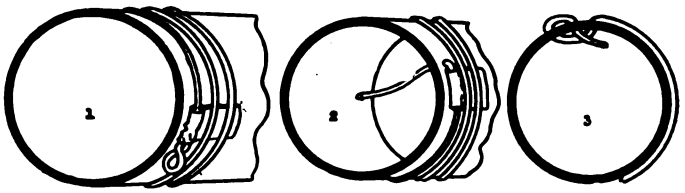

Fig. 5. Suggested method of fastening the first turn of the winding in order to prevent working loose. A strip of adhesive tape will do nicely.

rather than on a ball, 2¾ inches in diameter and 1½ inches long. Allowing ¼-inch margin along each edge, there is winding space for 48 turns of No. 24 S. C. C. copper wire. These turns are wound continuously and are not tapped. Suggestions for beginning and ending the winding are given in Fig. 5. Whether or not these suggestions are followed is of no importance, but be sure that both leads are brought inside the coils before calling the winding complete. For in order to give the secondary coil some freedom of motion, it is necessary to bring the leads out by way of the tubular shaft upon which the secondary is rotated.

This is done by drilling two holes in the shaft to the rear of the second bolt. The holes should be about ⅛-inch in diameter, or large enough to permit the passage of spaghetti tubing. They enter the tube from opposite sides and only penetrate halfway. The spaghetti tubing is then forced into the holes and out through the shaft at the rear of the coupler. The leads are then put through the spaghetti insulation, and they come out as shown in both Fig. 1 and Fig. 4.

The assembly drawing does not show the seven-point switch needed for the primary of this coupler. Otherwise, however, it is complete, showing the mounting of the instrument as well as the manner of its operation. In using a variocoupler in connection with a regenerative set, many amateurs employ the primary as a tuning inductance and the secondary as a tickler or feed-back inductance. This particular instrument works at its best with such an arrangement, but it is also supremely well adapted to every use to which other, and not so modern, couplers may be put.

A HALF - INCH RADIO RECEIVER

A radio receiving set so small that it can be used to replace the jewel in a lady's hat pin has been built by Allen Turner, of Los Angeles, California. The illustration on the right shows a view of the receiver, whose small size can be appreciated by comparing it with the fountain pen held alongside of it.

A Rectifier Made from Odds and Ends

By Ted C. Van Alstyne

FOR many people the stumbling block in radio is keeping the storage batteries charged. Lugging a forty or fifty pound battery to and from the garage is no easy task, especially if the garage is some distance away. Also, manufactured chargers come at high prices. The alternative then is to build your own rectifier to change the alternating current from the lighting circuit to a direct current to charge your battery.

An efficient rectifier can be made from odds and ends found in the cellar, dusted off and brought down from the attic or purchased at a figure within reach of all radio enthusiasts. If the instrument described in this article is carefully constructed it will be found adequate to charge a battery from which one or two bulbs are operated daily.

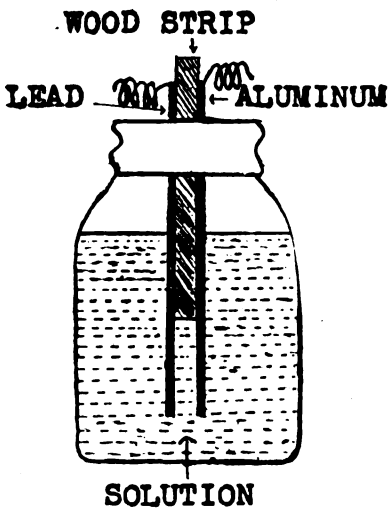

Fig. 1. Schematic drawing illustrating the method pursued in making up and arranging the elements of the rectifier.

First obtain from the top shelf in the pantry four wide-necked jars. The wider the tops the better. Fruit jars will do nicely. While you are in the pantry get the wife's supply of baking soda and bring it to the work bench. Cut from sheet aluminum four pieces six inches long and as wide as will go in the jars. About two inches will be the maximum width if fruit jars are used. Also make four pieces the same dimensions from sheet lead. If you have no lead, sheet iron or steel will do. It does not matter much about the thickness.

Screw one piece of aluminum and one piece of lead (iron or steel) to each side of a wooden separator ⅜-inch thick, four inches long and as wide as the metal elements, as shown inside the jar in Fig. 1. Make sure the screws do not go right through the wood and touch the other sheet of metal on the opposite side. The aluminum plates are the rectifying plates. The more surface exposed in the solution to follow, the more current will pass and thus charge your battery that much quicker. Small screws or nails driven into the edge of the separator at a point where they will rest on the edge of the container jar will keep the completed element in place and prevent a slipdown into the mixture.

Now obtain three quarts of distilled water. If you have no still and your neighbor is using his get it from a garage or a drug store. Saturate the water with the wife's baking soda. That is, add the soda until the water will not dissolve any more. An ammonium phosphate mixture is also good.

Next make a lamp bank from four ordinary electric bulbs and sockets. Old carbon bulbs discarded for their dimness or used in the cellar will be just as good as new ones. Fuse cut-outs will serve admirably for sockets if you have any on hand. This lamp bank is necessary to make up the resistance of the circuit so your new contrivance will not blow the fuses.

Connect a double-pole double-throw switch to your battery and rectifier, as shown in the complete hook-up in Fig. 2. This will facilitate a quick change-over from charging to ready for use. A snap switch will suffice for shutting off the alternating current power.

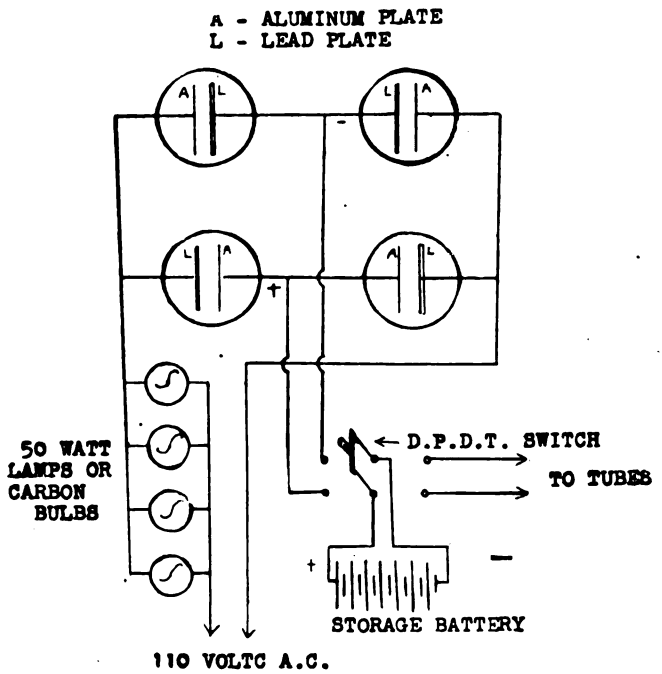

Fig. 2. Diagram showing how the rectifier should be hooked up, and also the method of connecting the series parallel bank of lamps.

The jars should be set in a tank about up to their necks in cold water to keep them cool. I used a cracker box of the well known tin variety. You will find that the jars heat a little when operated for a continuous period and the rectifying qualities diminish when this takes place, thus making the charging of your battery a slower process.

If the elements of each jar are connected with copper or brass ribbon and the cracker box given a coat of black enamel the finished instrument will have an attractive appearance.

When wiring the rectifier be sure the polarity is correct. Connect the aluminum plates through the change-over switch to the positive of the battery. The rectifier acts as a valve and allows the current to pass in one direction only—that is, from lead to aluminum plates.

Every two or three months empty out the solution and refill with fresh distilled water and a new supply of baking soda. Try the other chemical mentioned if you wish. You may find it necessary to replace the aluminum plates. Use only good metal. An alloy does not bring good results.

The weak spot in this type of charger is slowness.

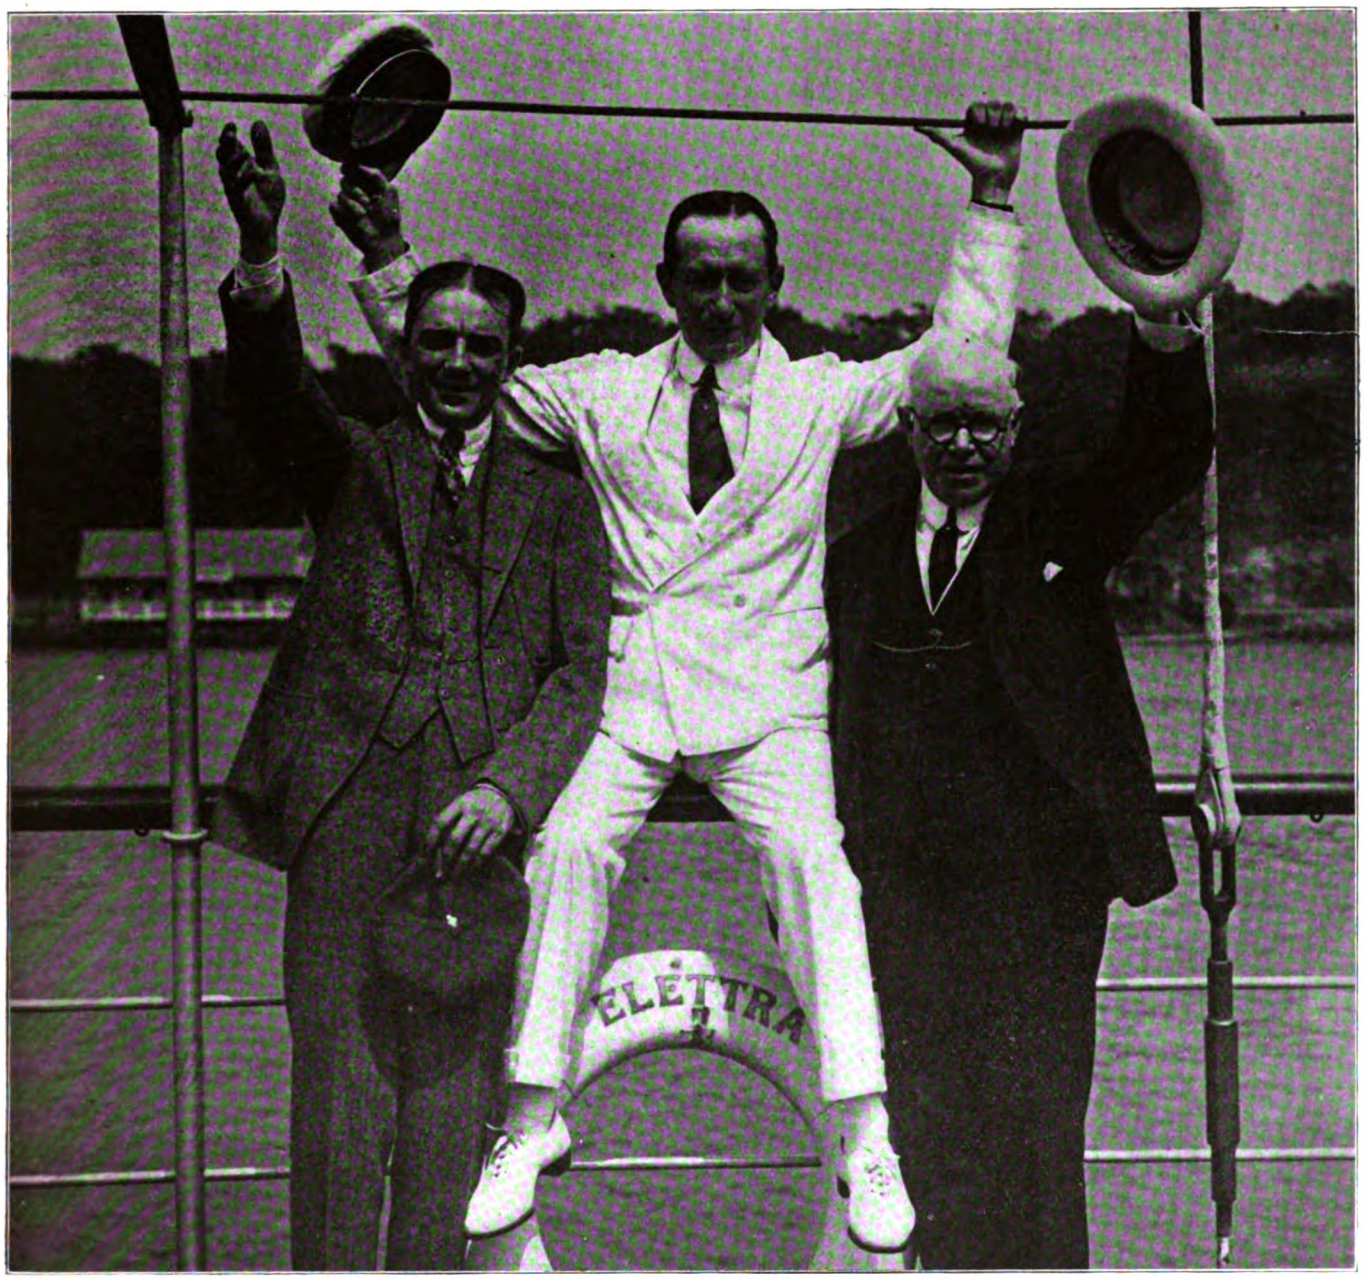
Marconi Perfecting Wireless Directional Control



(C. Underwood and Underwood)

This picture shows three of the foremost radio men in the world—Senatore Guglielmo Marconi, Owen D. Young and E. J. Nally—on the deck of Marconi's yacht, "Elettra." This photograph was taken on the occasion of Marconi's visit to Dr. Steinmetz, the famous electrical authority, and is one of the few photographs snapped of the wireless wizard when he was not working.

RADIO enthusiasts all over the country were greatly interested in the announcement from London last week that William Marconi, the eminent wireless pioneer, is confident of the successful development of a method of wireless directional control with which he has been experimenting. The inventor was quoted as saying that he hoped soon to perfect a device by which radio messages would be received only by the person or station for whom they are intended.

Mr. Marconi will conduct further experiments during April on his yacht "Elettra" off the coast of Spain, where he will receive messages from the station at Carnarvon, Wales.

It is understood in London that the device under development somewhat resembles receiving instruments by means of which stations are enabled to locate within a fraction of a second of arc the point of origin of the waves carrying messages.

"If my new device is successful, as regards controlling the air waves which carry messages, it will prevent waves spreading as they do now," Mr. Marconi is quoted as saying. "I can't go into details about it as yet. I hope it may be practical to regulate air waves, even as far as across the Atlantic. On my trip I am going south so as to be near port, instead of in mid-ocean, and we will try our tests on the far countries."

If the experiments are successful they will revolutionize existing radio so that messages will be received only by the station toward which they are directed.

California Leads the States in Number of Broadcasters

CALIFORNIA still continues to lead in number of broadcasting stations, with 59 in operation, while Texas has climbed to second place with 36. Every state, except Mississippi, had one or more stations on March 10 when the total of broadcasting stations had reached 588, the highest point since this service was undertaken in September, 1921.

Of these stations 66 represent educational institutions and 67 are newspapers and periodicals dispensing information and news as well as entertainment. Several cities, a number of churches, theatres and, of course, many electrical apparatus manufacturers and distributors are also included. The number of stations in each state as of March 10 follows:

California	59	South Carolina	6	Missouri	25
Texas	36	Alabama	5	Washington	24
Ohio	31	Arizona	5	Illinois	24
New York	30	Idaho	5	Nebraska	23
Pennsylvania	28	Maryland	5	Kansas	19
Iowa	26	Montana	5	Oregon	16
				Indiana	15
				Colorado	15
				Michigan	14
				Minnesota	14
				New Jersey	13
				Wisconsin	11
				Florida	11
				Georgia	10
				Massachusetts	10
				District of Columbia	9
				Oklahoma	8
				Louisiana	8
				Connecticut	7
				Kentucky	7
				Arkansas	6
				North Dakota	5
				Tennessee	5
				Utah	5
				Rhode Island	4
				South Dakota	4
				Wyoming	4
				North Carolina	4
				Virginia	4
				Delaware	3
				Hawaii	3
				Maine	3
				Vermont	3
				West Virginia	3
				New Mexico	2
				Nevada	2
				Porto Rico	2
				Alaska	1
				New Hampshire	1
				Mississippi	0
				Total	588

Radio Popular With Yachtswomen

(C. Gilliams Service)

As sailing days come nearer, yacht owners are equipping their craft with the latest in radio, not only as a pastime, but as a safeguard. The above illustration shows a fair yachtswoman on one of the many craft that hover all year round off the Pacific Coast, enjoying a pleasant moment listening in to the program being broadcast from one of the powerful western stations. This pastime has become so popular that now, instead of thinking what color they are going to paint the craft, they are asking, "Where can I put my antenna?"

Gov. Smith's Family Enjoy Radio

(C. Keystone View Co.)

Governor Smith, of New York, when he does get a few moments to spend, generally turns to his radio receiver and listens in. His family have all been ardent radio fans and Governor Smith himself is said to be a "mean dial twister." The above illustration shows the Governor's family listening in on the latest Radiola set, designed and made by the Radio Corporation of America.

Panama Will Broadcast

AN agreement with the Panama Government places the control of all radio in the Canal Zone or in the Republic of Panama under the United States, and the Navy acts for the Government. Panama would like to break this treaty, it is said, and either set up stations of her own or let commercial concessions open stations there. Broadcasting and radiotelephony have accentuated this, and commercial companies desirous of selling their equipment are no doubt behind some of these activities. The Navy has authorized the stations in the Zone to broadcast entertainment programs.

Norwegian Broadcasting

THE Norwegian telegraph administration requires that a company to which a broadcasting license is issued must be a stock company backed by native capital, in which Norwegian radio manufacturers, press and local amusement syndicates are interested. Broadcasting is limited to entertainment, information and news, Consul Carlson at Christiania reports.

The station at Christiania will be used, it is said, for experimental work, but the matter transmitted will be "censored and edited" by the administration. Receiving licenses will be required and a charge will be made for them. Only Norwegian sets can be used it is understood, and although the company is not to have a monopoly on receiving sets, remuneration may be charged for broadcasting service subject to the approval of the Government.

Secretary Hoover Wants Executive Order to Relieve Radio Congestion

THE Second National Radio Conference was opened in Washington, D.C., on March 20, 1923, by Secretary Hoover, of the Department of Commerce. President Harding will be asked to solve the difficulties now existing in radio broadcasting by issuance of an executive order putting into effect recommendations to be drawn by the conference. This action was made necessary by the failure of the recent Congress to pass legislation enabling the Department of Commerce to exercise proper control.

Secretary Hoover stated to the conference that the situation regarding interference of conflicting messages in the air had become worse than it was when the matter was laid before the law makers. The House passed a bill, but the Senate failed to reach it.

Since the first radio conference was held a year ago the use of radio has grown tremendously making it necessary, according to Mr. Hoover, to find new radio paths for broadcasting. At present there are 588 broadcasting stations where there were but 60 one year ago. Secretary Hoover suggested that by executive order it would be possible to open up to private stations the use of wave lengths between 600 and 1,600 meters, now limited to the Government.

General Squier of the Signal Corps emphasized the importance of reserving for the Government the right to use its own wave length in times of emergency, but could see no objection to relinquishing this exclusive privilege temporarily. Commander Bingham of the Navy said certain mobile branches of the Government had been overlooked in the allocation of wave lengths.

Amateur radio enthusiasts were advised that in the absence of a law on the matter their co-operation was essential to best results.

The statement made by Secretary Hoover at the opening of the conference follows:

The Department of Commerce has asked for the assistance of representatives of the various Government departments and of the various sections of the industry and of the profession surrounding the radio work to determine if it is possible to do something from an administrative point of view that will relieve the present interference and congestion in broadcasting.

You will recollect that we held a conference of this character almost twelve months ago, and the gentlemen who comprise the committee of the conference are much the same, with such replacements or such changes in Government representation as have been necessary.

At that time we considered the whole problem of interference for the purpose of making recommendations to Congress with a view to legislation that would relieve the difficulties. The legislation was presented to Congress; it passed the House, but failed in the Senate due to the congestion of other work. The consequence is that we have found no relief for the public and in the meantime the situation has become even worse than we could have anticipated.

At the time of the conference a year ago there were about 60 broadcasting stations, wheras today there are 588. At that time we estimated that there were something like 600,000 to 1,000,000 receivers, and now the estimates run from 1,500,000 to 2,500,000.

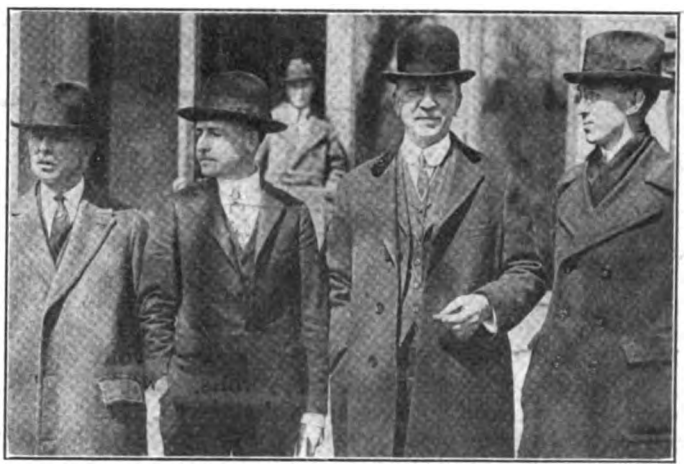
Public broadcasting has practically been limited to two wave lengths, and I need not dilate to you on the amount of interference there is and the jeopardy in which the whole development of the art stands. We must try to find some sort of solution by expanding the number of wave lengths available for public broadcasting.

The purpose of this conference is not to consider legislative questions but solely to consider what may be done by way of increasing the number of wave lengths, or wave bands, available for general broadcasting purposes.

As you are aware, the area from 600 to 1,600 meters is reserved for Government use. But if it meets the approval of the conference, the department will recommend to the President that some opening shall be made in that area for general broadcasting, to be accomplished by executive order.

The question is not so simple as it might appear on its face. The development of the art seems to show that the lower ranges of wave lengths are probably of more service in public broadcasting than the higher ranges, and it is of importance in developing the use of public broadcasting that we take no step that will interfere with the future development of the art and that whatever steps we do take, although they may be tentative in character, shall be constructively drafted in the direction of the best development of the industry and the art itself.

I have felt that the question involved in so important a method of communication perhaps only in its earliest stages of development, is so great and so important that we wish,



(C. Underwood and Underwood)

Government representatives at the Second Radio Conference, Washington, D. C., called to discuss methods of alleviating radio broadcasting congestion. Left to right: W. D. Terrell, Chief Radio Inspector, Department of Commerce; Dr. J. H. Dillinger, Chief of the Radio Laboratory, Bureau of Standards; D. B. Carson, Commissioner of Navigation, and L. E. Whittemore, Bureau of Standards.

that we must have, the best advice and cooperation from everyone who can contribute useful and thoughtful suggestions.

Due to failure of the legislation we are left without the necessary authority to effectually prevent interference. In seeking this authority we were supported by literally the entire radio public. They wanted to be regulated. We are now left where, if we accomplish anything, it must be by organized cooperation during the next year.

We have made the conference public. We are asking that everyone who can contribute some suggestion shall do so, and, in fact, we request anyone to appear who can be of service and give us the best of his advice.

We have had some study made of the problem by a group of men peculiarly able to give advice, that is the radio inspectors of the country. They have had to deal during the last twelve months with the complex problem of interference and a thousand difficulties; and in order that their views should be well formulated for the conference they have been in session for some time and have brought in a definite memorandum of suggestions. I thought that such a memorandum would be of more constructive assistance on their part than a public presentation of their views.

The Radio Primer

For Thousands of Beginners Who Are Coming Into Radio Circles

Weekly A B C of Radio Facts and Principles Fully and Clearly Explained

By Lynn Brooks

IN the construction of single-circuit sets, what are some of the points of caution to be observed in order to make sure of the efficient operation of the circuit?

In the construction of the single-circuit set, which is the simplest circuit for the uninitiated constructor, the following precautions should be observed: The leads should be soldered for the best efficiency. Short leads should be used rather than strictly right-angle connections. The leads from the tube, such as the grid leak lead and plate lead, should all be made separately, and not tapped onto one another. The leads from the tickler should be made correctly, as the circuit will not function properly otherwise.

* * *

Is there any advantage to be gained by the use of double-circuit jacks in a set that comprises more than one tube?

The advantage gained by the little extra work in connecting up a double-circuit jack in a set that comprises more than a single tube is that there is no chance for any current being dissipated through leakage in the primary of the transformer. It also has the advantage of preventing any trouble arising from current leaking, as before stated, and setting up a back feed which might cause squeals and howls that would be objectionable.

* * *

Is a filament rheostat absolutely necessary in the use of the 1½-volt tubes?

This is a question that has been asked many times because of the fact that the tube takes 1½ volts and the dry cells are meant to furnish 1½ volts. While the 1½-volt tubes will, and do, take 1½ volts, they will often work more efficiently on much less, frequently taking not more than one-quarter of the actual voltage rating for their efficient operation. It is therefore absolutely necessary, for the correct functioning of the tube, to provide a rheostat for the control of the filament current.

* * *

Why is it possible to hear a squeal in a non-oscillating set when tuning in stations where they are nearly on the same wave length?

This is due to the fact that the two carrier waves of the transmitters conflict with each other, producing a "beat" note, which is audible. It is the same in basic principle as hetrodyning a non-regenerative set through the agency of a nearby oscillator.

* * *

Is the squealing above mentioned preventable?

This cannot be prevented because of the fact that, even though the set is not oscillating, the beat note will be audible, as explained before, and also because a set which does not produce oscillations of its own accord is not as sharp in tuning as one that oscillates.

* * *

When a receiver squeals over a wide scale without a station being heard, what is the trouble?

When this squeal occurs it indicates that the tube is being forced, and the following should be done: The filament current should be reduced; there should be less B battery used, and occasionally the trouble will be eliminated by varying the grid leak. Either lessening or increasing the resistance in the grid leak for each particular tube often stops this squeal.

* * *

In the use of some tubes microphonic noises are often heard, some to such an extent that it is unpleasant. Mention some ways of preventing this.

These microphonic noises, which are due to vibrations of the elements inside the tube, can be eliminated in the following manner: The tube socket should be mounted on heavy, thick felt, or very soft rubber, and no direct connection, such as screws, should hold the base of the socket to the base on which it is mounted. Another method is to mount the sockets on a sub-panel, which is suspended on springs, or strips of thick rubber, so that any vibrations will not be transmitted to the tube itself.

* * *

What is the correct position for the mounting of a tube? Does the position have anything to do with its operation?

In the mounting of tube sockets relative to the position of the filament the following should be observed: The tube should be mounted in such a manner that the filament is vertical. The reason for this is that, if the filament is mounted horizontally, it will sag, due to the heat expanding the filament, and in time will touch one of the other elements, which will short it. The position in which a tube is mounted has nothing to do with its operation. It is simply a matter of the care of the tube that it should be mounted as above outlined.

* * *

Is there any method of renewing the life of a tube after it has been shorted other than having it repaired?

A tube which is blown cannot be repaired, as can a light bulb, by tapping on the glass and fusing the ends of the filament together because of the fact that the filament is short and is stretched on holders that tend to keep it tight. When it is burnt out it is useless to attempt to renew it. Have a new filament put in.

* * *

What are "long-armed controls"?

"Long-armed controls" is a coined term to designate an extension on the tuning controls, generally a long piece of hard rubber tubing, which will allow the various controls to be manipulated without the necessity of bringing the body of the operator near enough to the set to allow the body to have the capacity effect.

* * *

Which is the best of the three methods of eliminating body capacity?

In the long run, it will be found that the shielding of the panel will give the most satisfaction, although the other methods outlined last week may be successfully employed. The shielding, however, will absolutely prevent any capacity effect being felt at all, while there is always the liability of the other methods not being efficacious enough to eliminate it entirely. This, of course, can be determined only by actual experiment.

* * *

Will the shielding of the panel eliminate the capacity effect felt in the phone circuit when the phone cords are grasped?

The capacity effect noticeable in the phone circuit cannot be eliminated by shielding the panel, and as a matter of fact it is almost impossible to eliminate it. This effect is noticed only when the body is very near the cords themselves. If the phone cords are left lying on the operating table without being held or moved away from the body, the capacity will remain constant and the capacity effect will not be noticed except when the arm or hand lies on top of the cords.

Radio and the Woman

By Crystal D. Tector

THE doctor who lives next door to us has finally been invoked into the Radio Clan. And it really was funny how long he held off and what reasons he had for delaying the purchase of his set. He said that the constant listening-in was harmful to the ears, as it strained the nerves. But his wife, who by the way, is the president of our Matinee Club, kept after him for so long that he finally got a little bit of a crystal set, and had it two days, when he went down to New York one afternoon and ordered a set direct from the manufacturer. And now F. H. is jealous of it because it is more up to date than ours, but I say, "We'll let our Flewelling alone for a while, until you get up ambition enough to make one for yourself. I'm not going to let another manufactured set into this house until you show me that you can do as well as I did with mine." And that ends it.

* * *

I have been impressed so deeply and so often lately by the remarkable influence of radio on the country as a whole, that I have begun to take the indications of its far-reaching effects on the average person as a matter of course, and as the inevitable result of its widespread appeal and scientific worth. But when I accepted the invitation of a friend of mine to have dinner at her home recently, I little expected at the time that I was to witness again a specific instance of the happiness and contentment that radio brings into many homes.

My friend's mother is blind. The full significance of such an affliction cannot possibly be realized by those who are fortunate enough to be blessed with unimpaired sight. The ordinary pleasures, such as the movies, the theatre, the daily newspaper and books, are denied those who have lost their sight. But now we have radio.

No more need for those who are afflicted with blindness to sit through the long days in darkness. Radio has opened up the world to their sightless eyes through the medium of forgetfulness and the enjoyment born of "listening in." As I walked into the living room of my friend's home, the first thing to attract and hold my attention was the sight of a kindly, gentle little lady, sitting in her armchair, with a smile of contentment on her face. On her ears were a pair of phones. As I entered, she reached over to the radio set on the table by her chair, "tuned out," and greeted me in a manner more cheerful than I had ever noticed in her before.

"My dear," she said, "there are a great many things in life that seem unbearable at times. Until recently, I thought that blindness was one of them. But since Alice bought me this radio set, and taught me how to 'tune in' on the world, I think I have found at least partial compensation for the loss of my sight."

And before the evening was over, I knew by her animated conversation and the expression of happiness on her face that radio had made one more conquest; had brought joy and gladness into one more home, and I left with a still stronger feeling of thankfulness for the service it renders those whose lives previously had been lived in the shadows.

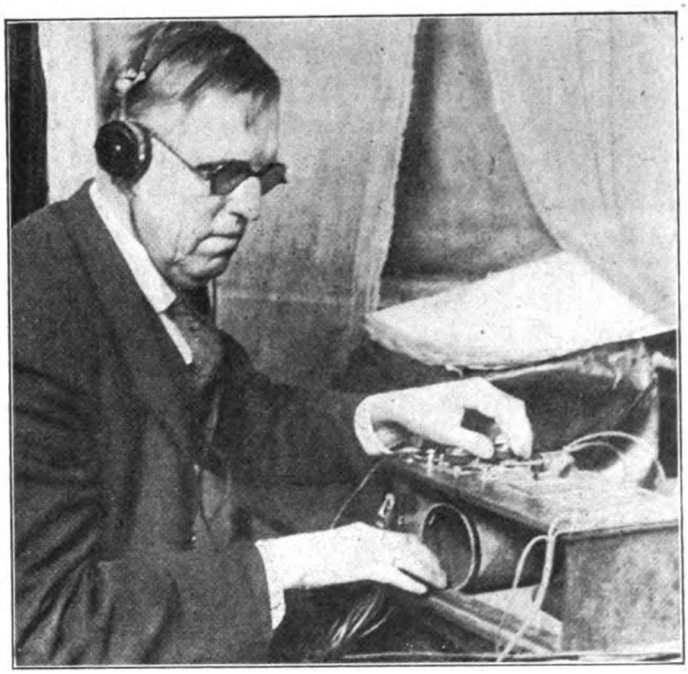
* * *

A friend of ours recently visited us, and upon seeing that we had a radio set told us that Billie, her son, had been bothering her to allow him to install one, but that she was afraid that it would be dangerous. "You know that with all those big stations sending, I thought that it would shock him, and probably kill him, poor dear." Well, I just laughed out so loud that she was very indignant, but when I explained that there was less danger of getting hurt from radio than there was in crossing 42nd street and Broadway at four o'clock in the morning, she sort of smiled weakly and in such a way that said, "Well that may be so, but I don't believe it." So I went into a long discourse and told her all about the way in which it was done, and I believe that she was convinced. You can just imagine my surprise when Billie called me up and told me to come over and "see the wonderful set Ma bought me for getting a good report card." Well, I thought that I was pretty good when I sold a booth at the county fair, but I think that I can pin a medal on my "Sunday go to meetin'" suit for that. The idea of anybody being afraid of anything these days. Why, I don't have a ground switch on our set, being confident in the lightning arrester that I have installed.

* * *

I ran in to see Ye Editor last week and he told me that my next contribution would be for RADIO WORLD'S birthday. Just think of it, folks, it's one year old this week and still growing better and better every day. I know that I am simply tickled to death, and the fact that he said that he was going to put a Special Dress on our magazine just made me leap with ecstacy. And the ads. Why, I never even saw anything like it. And to think that I am a part of it all!

Blind—Makes Own Receiver



(C. Keystone View Co.)

Clemens C. Niemeyer, of St. Paul, Minn., although blind, is not in the least handicapped. Being an ardent fan, he not only built his own set, but made three others for friends. He is fifty-eight years old, a piano tuner by trade and spends his spare time making sets and listening in. He winds the coils himself, and does everything, even to making the cabinets, which is in itself a job that a whole lot of amateurs would not tackle.

The Neutrodyne Circuit Receiver

By Kimball Houton Stark

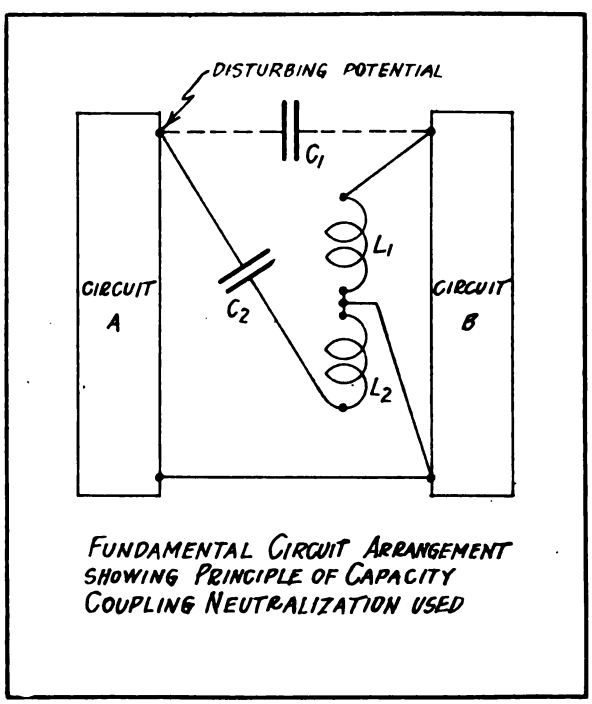
Chief Engineer, F. A. D. Andrea, Inc.

POSSIBLY the newest development in radio is the neutrodyne circuit invented and developed by Professor L. A. Hazeltine, professor of Electrical Engineering, at Stevens Institute of Technology, Hoboken, N. J.

Professor Hazeltine recently disclosed his circuits before a meeting of the Radio Club of America at Columbia University, New York City.

The object of the neutrodyne circuit is the neutralization of the capacity coupling between two or more portions of a given circuit. When used for the improvement of radio receiver circuits it eliminates the capacity coupling existing between plate and grid, thus preventing regeneration. This condition of neutralization is brought about by the adjustment of specially designed condensers placed in the circuit.

The fundamental circuit illustrating the neutrodyne principle is shown in Fig. 1. In the diagram, circuits A and B are coupled through the direct connection at the bottom and through the coupling capacity C1. To neutralize this capacity coupling two closely coupled

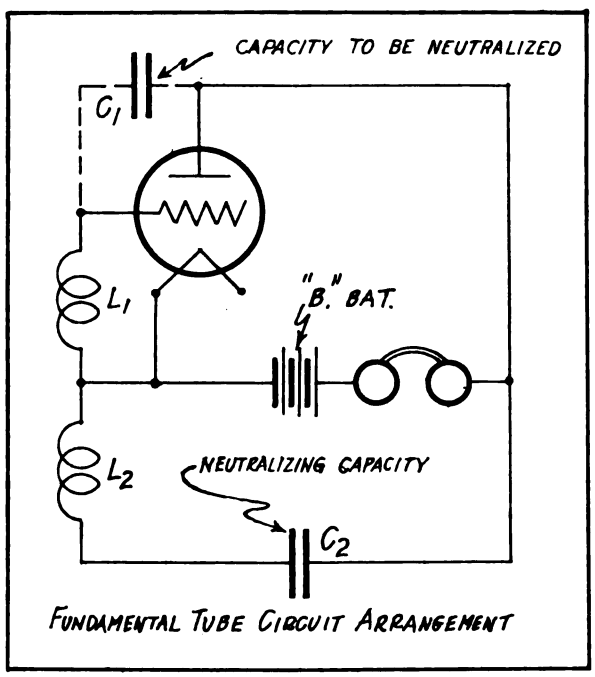


FUNDAMENTAL CIRCUIT ARRANGEMENT SHOWING PRINCIPLE OF CAPACITY COUPLING NEUTRALIZATION USED

inductances L1 and L2 and the neutralizing capacity C2, are arranged as shown, L1 being connected between one terminal on C1 and the common connection, and L2 being being connected in series with C2, between the other terminal on C1, and the common connection. Terminals of L1 and L2 which are connected together are of unlike polarity. If circuit A has a source of alternating current, the alternating potential at its upper terminal (marked disturbing potential) will send a current through C1 to circuit B, which current in flowing through the impedance of circuit B, will set up a voltage between the terminals of this circuit, power thus being transferred from A to B.

Now if the neutralizing circuit L1, L2 and C2 be introduced and so adjusted that the current through L1 magnetically balances the current through L2, no voltage will exist across either of these coils nor across circuit B, which is the condition desired to eliminate the transfer of energy.

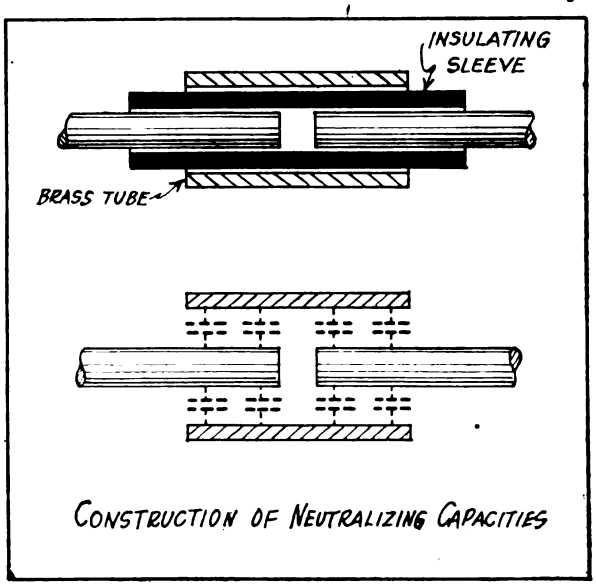
As directly applied to vacuum tube circuits, Fig. 2 illustrates the application. In this figure, the capacity C2, being correctly adjusted, neutralizes the grid-plate capacity, represented by C1.



FUNDAMENTAL TUBE CIRCUIT ARRANGEMENT

In actual practice inductance coils L1 and L2 may be respectively the primary and secondary inductances of air core radio frequency transformers. The secondaries of these transformers are preferably tuned by variable air condensers. A distinct advantage of the neutrodyne circuit is the fact that radio frequency transformers may be employed having a step-up ratio of windings of the order of one to four.

The adjustable neutralizing capacity in both Figs. 1 and 2 is designated as C2. In actual practice this capacity is adjusted in such a manner that the capacity



CONSTRUCTION OF NEUTRALIZING CAPACITIES

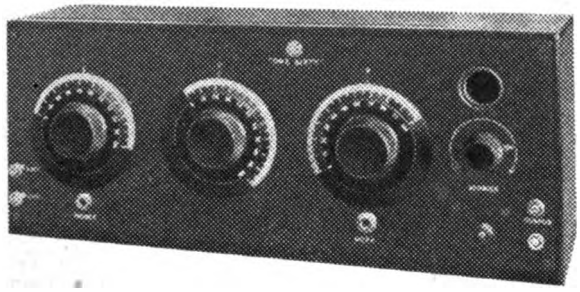
coupling between circuits is reduced to a minimum, if not to zero. The neutralizing capacity may have a capacitance of from 1 to 5 or 6 micro-micro-farads.

(Continued on following page)

Digitized by Google

(Continued from preceding page)

Such a very small adjustable condenser is unusual even in radio. A condenser of this kind may be readily constructed as shown by the drawings in Fig. 3. It consists of an insulated sleeve in which are inserted two pieces of wire with about ⅛ inch space between them at the center. A metal tube is then adjusted lengthwise from the ends of the two wires, the resultant capacity being the series capacity of the metal tube and both wires. During tests this neutralizing capacity is adjusted and then sealed.



In making this initial adjustment, the receiver circuits are tuned to a strong buzzer signal, the filament of the tube whose capacity is to be neutralized is turned out, but the tube left in its socket. When the neutralizing capacity is properly adjusted under these conditions there will be no capacity coupling on either side of the tube and no buzzer signals will be transferred. If the tube, however, is taken out of the socket altogether signals will come in strong, being again neutralized when the tube is placed in contact with the grid and plate contact springs.

Such a method of adjustment illustrates that the neutrodyne circuit operates to eliminate capacity coupling and is not just a method for opposing the effects of regeneration, because the adjustment is made with the filament cold, and therefore, under conditions when the tube could have no regeneration.

controls. Three of these are large dials for tuning control and the fourth knob is that of a vernier rheostat for the detector tube. A switch is shown at the lower right hand end of the panel for tuning on and off the filament current to all tubes.

In the interior view, Fig. 5, the radio frequency transformer units are shown mounted at such an angle to each other that no transfer of electro-magnetic coupling can take place. The neutralizing or balancing capacities are shown above and between the transformer units.

Fig. 6 shows a complete schematic wiring diagram of the receivers illustrated in Figs. 4 and 5. The table of constants beneath the wiring diagram will explain the various parts of the circuit. This circuit using only four tubes actually does the work of five tubes as the first tube is used as both a radio and audio frequency amplifier.

It seems to be human nature for every one who owns any kind of a radio receiver to want to pull in long distance signals. To get stations a thousand miles away isn't enough, and we are continually staying up nights twisting dial after dial in an effort to bring in that station 1,500 or 2,000 miles away.

From this point of view receivers utilizing the neutrodyne circuit are certainly ideal. There being only three simple adjustments, nearly any one can learn to operate the receiver in a few moments and with exceptional results. In such a receiver, there being no regeneration and no re-radiation, obviously there will be no squealing and howling and interference will not be caused in passing over various carrier waves.

Radiograms

It is rumored that the French Line will equip all its passenger ships sailing out of New York with radio receivers and amplifiers for the reception of broadcast programs.

* * *

For the second time in a fortnight American concerts were heard in France when Paris wireless amateurs last week listened in on the Wanamaker organ recital broadcast from Philadelphia.

* * *

In January, 1921, a transcontinental amateur record of 6½ minutes for sending a radio message across the United States and return was established. Efforts to eclipse this record across Canada, from Montreal, P. Q., to Vancouver, B. C., will be made by amateurs this week.

* * *

Jane Cowl's interpretation of Juliet was broadcast one night last week across the entire country from Henry Miller's Theatre, New York City, where Miss Cowl is beginning her third month in "Romeo and Juliet." She gave the entire first act of Shakespeare's tragic love story to the United States by radio.

* * *

Free medical advice via wireless to Swedish ships at sea will be given on demand from leading hospitals in Stockholm and Gothenburg, providing the Swedish Government grants the request of the Department of Telegraphs to transmit such advice without cost. Sweden will be the first country in Europe to inagurate this kind of service, already tried out in this country.

* * *

Many thousands throughout the South who "listened in" on Atlanta, Ga., on a recent night learned something of the magnitude of the automobile industry directly from the lips of C. W. Nash, president of the Nash Motors Company. Mr. Nash spoke from the office of the Atlanta Journal. It was pointed out that in value of finished product the automobile industry ranks first in America, exceeding by a generous margin even the gigantic steel and textile industries.

* * *

The Monte Grande wireless station near Buenos Aires, Argentina, the first South American station in the international commercial radio system, is almost completed. It will begin service some time next summer. Argentina will then be placed in direct wireless communication with the United States for the first time, as well as with Europe. It is said that there are two strange, static "dead areas"—one near the equator off Brazil, and one in the South Atlantic—which only a station equipped like that at Monte Grand can overcome. The new station has been built entirely with American materials.

* * *

Before long a complete radio installation may be expected with every one of those homes on which you pay down all you could save in a lifetime and then face four mortgages. Already several builders around New York have held forth this added inducement to quit the noisy city and live in our better radio circles, observes the New York "Times." The experienced suburbanite who goes forth to look at a house no longer asks how far it is to school, whether city improvements have been made and what days the trains do not run. Instead, he talks about aerials, antennae, ground connections and all the other things that one has to have or do when he takes up radio.

A $1,200,000 real estate deal was completed by radio last week after E. Clifford Potter, cruising in the Mediterranean aboard the "Adriatic," had "sat in" with his colleagues in discussions of the deal in New York City.

* * *

Steel cages no longer prevent inmates of the Allegheny County Jail at Pittsburgh from enjoying the entertainments of the outside world. Warden Edward Lewis has installed a radio set, by which they nightly take "radio trips" to the various broadcasting stations.

* * *

A nation-wide survey by the Broadcasting Committee of the National Radio Chamber of Commerce discloses that "congestion of radio communication has increased to such an extent that the value of this medium to the public is seriously endangered by the resulting interference."

* * *

The Newspaper Proprietors' Association and the Newspaper Society in the British Isles have notified the Radio Broadcasting Company that no radio programs will hereafter be inserted unless paid for at regular rates. The broadcasting company replied that it would not use advertising space to announce its programs.

* * *

A report of the recent Firpo-Brennan prize fight by rounds was transmitted directly from a New York City broadcasting station and picked up at Saavedra, near Buenos Ayres, and was relayed by telephone to the newspapers in the city. It is claimed this was the first time that radio communication between the United States and Argentina was established successfully.

* * *

Receipt by the State Department of a report by the Commission of Jurists which met at The Hague last December is now followed by an announcement by Secretary Hughes that the Government might initiate action looking toward a treaty or a convention among various nations based upon the report as it affects rules of international law applying to radio and aircraft.

* * *

Just as radio is becoming so popular a new type of crook, the radio burglar shows up, taking the place of the sneak thief who a few years ago grew rich by gaining access to homes on the pretext that he was a telephone repair man. This is the assertion of the chief investigator for the burglary department of a New York casualty company, in issuing a warning to amateur radio fans not to admit to their homes radio repair men unless they can show credentials.

* * *

The medical profession has often been reproached with conservatism, but this tendency has not prevented the growing use of radio apparatus in the hospital, says Dr. Albert S. Hyman, of the Mount Sinai Hospital, Philadelphia, writing in "Hospital Management." It is Dr. Hyman's belief that radio equipment has a distinct and beneficial use in hospitals, particularly in those dedicated to the relief and convalescence of chronically ill patients, and to institutions situated afar from the large centers of population. The problem of keeping such patients interested in other things besides themselves, he says, is one which hospital administrators and others have pondered for many years. Occupational therapy, systematic exercises, physiotherapy, and allied fields are essentially devices for removing the patient from himself. To these has now been added radio.

(*Continued from page* 21)

that Dials 2 and 3 will read nearly the same, Dial 1 varying in setting with various antennae used.

Once a station is logged and notations made of the settings of all three dials the same station can be listened to at any later time by simply readjusting the dials to the given setting.

Some of the broadcasting stations heard from New York using only a 50-foot indoor antenna around the picture moulding of a fourth floor apartment are noted below together with dial settings. This reception was on the evening of March 8, 1923.

STATIONS HEARD FROM NEW YORK ON RECEIVER USING HAZELTINE'S NEUTRODYNE CIRCUIT

A Low Power C. W. Transmitter

By C. White, Consulting Engineer

WELL do I remember in the early days of radio when the owner of a vacuum tube was looked upon by his fellow fans as a sort of a "tin god." It so happened that one of these few "tin gods" lived in the next block and this particular fellow was an old chum of mine. We had both followed the science as closely as possible since in those days radio magazines were rather strange and unheard-of things. After the war we decided to carry on some experiments in radiophone which had been rather abruptly cut off. The first experiment was to develope a small transmitter. The transmitter was nothing more than a regenerative receiver with a microphone in the Ant.-Gnd. circuit. After much effort the set was so adjusted that radiophone messages could be sent from his house and received in mine on an ordinary crystal receiver I had always used for my code reception.

Amongst the C. W. amateurs the five-watt single tube transmitter is no doubt the most popular type. This type has won favor and its undisputed position owing to the fact that it is simple and extremely efficient. Its simplicity lies in the fact that no separate tube is used for modulation and its efficiency is due to the fact that it can be overloaded to a great extent without harm. In addition to these advantages it is extremely compact and when once correctly designed it works with the minimum number of controls. Of course, there are many types of tuning circuits that can be used with five-watt transmitters. The coupled circuit type and the single circuit type, or a sort of combination type, are most used. Then again, they can be classified in regard to style of modulation—direct carrier modulation, indirect carrier modulation, and direct buzzer modulation. Direct carrier modulation consists in placing the microphone in series with output of the oscillator and by talking into the microphone the resistance from aerial to ground is accordingly varied and hence the amplitudes of the carrier waves radiated from the antennae are functions of the microphone resistance. Such a method is not so very satisfactory since it is next to impossible to secure a good degree of variation in carrier wave amplitude. It is simple and effective in producing a rather pure modulation but poor in efficiency because only a relatively small audio-frequency is impressed upon the oscillator output. The indirect method makes use of a modulation transformer which serves a double purpose. This transformer not only steps up the audio-frequency voltage variations, but also acts as a filter in preventing the direct current flowing in the microphone circuit from associating with any of the currents in the oscillator. The advantages of this method of modulation are better control of the audio-waves through the variation of the direct current flowing through the microphone and more complete modulation of the carrier since this type of control is afforded.

In Fig. 1 is illustrated a simple type of single tube transmitter. The tuning inductance L is nothing more than the old double slider tuning coil type which is familiar to all and easily purchased or constructed. The condenser C-1 is a 23-plate air variable, C-2 is a .00025 micro-farad mica, and C-3 is a telephone type of condenser whose correct value of capacity will depend upon the make of modulation transformer employed. The amateur builder can easily ascertain the correct value to use by writing or inquiring of the manufacturer of the transformer. A condenser of .25 mfd. is quite often employed but sometimes smaller or larger ones are better with certain transformers. Likewise the value of grid leak will have to be determined by trial since each particular tube has a certain value of grid leak resistance at which it functions very much better than at any other value. The potentiometer P should have a resistance of 250 ohms and by its use it is possible to impress the correct potential on the grid of the tube, thus securing the point of maximum efficiency. The modulation transformer is so connected in the circuit that its output varies the impressed voltage on the grid of the tube, thus varying the amplitude of the oscillations being generated. If the amplitude of the voltage varied on the grid by means of the output from the modulating transformer be excessive the same will not only react to change the amplitude, but will also seriously disturb the oscillating balance of the transmitter and hence alter the wave-length of the

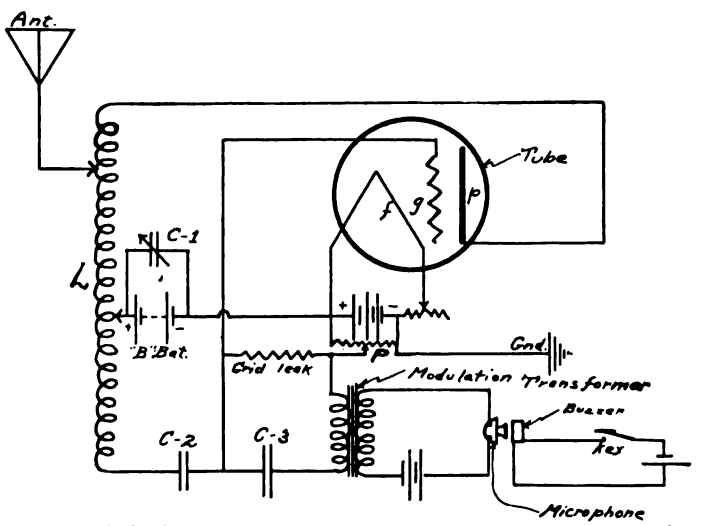

Diagram of the low power transmitter as described in the accompanying article. If the inductance L is constructed by the builder, extreme care should be taken in winding. Wire smaller than No. 22 should not be used. If a 5-watt tube is used larger wire should be used.

carrier wave in addition. Naturally this condition of affairs is quite undesirable, for the carrier wave frequency must not be altered by the modulating apparatus other than to the extent of the upper and lower side-bands. Such trouble is often removed by reducing the voltage of the battery in the microphone circuit.

In order to be able to transmit code when desired, a small high pitch buzzer should be included in the station equipment. By placing the buzzer close to the mouthpiece it is possible to transmit a clear characteristic note. If so desired greater modulation can be obtained when sending code by connecting the buzzer contacts in place of the micro-phone terminals, but the set is more flexible as illustrated. For local work the set can be used as a radiophone and for distant work buzzer modulated signals can be sent out over space. Of course, it is highly imperative to operate the set with a high plate voltage. The tube must be slightly overloaded in this regard in order to get good efficiency. Indicating instruments are a great aid in obtaining consistent results night after night. With but little experience the operator can easily tell if something has gone wrong with his outfit. A hot wire ammeter in series with the antennae and a similar type of ammeter in series with the plate of the tube will greatly aid the operator.

ts Third Volume With This ay Caught By the Camera

Robert L. Dougherty

(C. Underwood and Underwood)

"Uncle Robert," who devotes his life to making things easier for the blind and otherwise unfortunately disabled, holding three-year-old Evelyn Kriloff, while she listens to the radio concert. Uncle Robert has done much to cheer the disabled.

(C. Underwood and Underwood)

The way they do it in the modern conservatory, as shown at the Third Annual Radio Convention, held at the Hotel Pennsylvania. The set is complete in itself, using a loop antenna and a loud speaker in conjunction with a powerful receiver.

(C. Kadel and Herbert)

William Henderson and his super-heterodyne receiver which he constructed after school hours. The receiver is of the eight-tube type and he has succeeded in picking up stations 2,500 miles away on the loud speaker, an accomplishment that is wonderful in itself.

(C. Fotograms, N. Y.)

Sir Gerald Du Maurier, noted English actor, is an ardent radio fan and has located his receiver in a sectional bookcase, so that it will be kept dust-proof when it is not in use. The set shown is of British manufacture and utilizes seven tubes. He has done some remarkable work with it.

(C. International Newsreel Photo)

An illustration showing that the United States is not the only place where radio is popular. A London family is here shown listening in to a play at the Hippodrome, just as the American fans listen in to opera.

Answers to Readers

I AM building a regenerative set incorporating one stage of radio frequency, detector and one stage of audio frequency. I am in doubt as to how to arrange the tubes, so am enclosing a sketch of how I intend to do it. Can you offer any suggestions as to a better manner?—Charles A. Galton, Bloomsburg Hosiery Mills, Bloomsburg, Pa.

The sketch you enclose is quite correct with one exception. The tubes preferably should be arranged in the following manner: Instead of detector, radio frequency amplifier, audio frequency amplifier, it would save wiring trouble and time if you arranged the sockets and wired them as radio frequency amplifier, detector and then audio frequency amplifier. This method will save lots of space, as you will then be running your wires in correct continuity with the phases in which the current travels through the circuit.

* * *

Where can I obtain a hook-up of the flivver set described in RADIO WORLD*?—Richard Jenkinson, 264 Liberty street, Paterson, N. J.*

If you will write to the Permanent Radio Fair, Hotel Imperial, New York City, you will be able to get the information you seek.

* * *

Kindly let me have a diagram for a stage of audio frequency to be added to my set. I already have detector and two stages and desire to add another stage. I have added two stages of radio frequency, but it doesn't seem to make the signals louder at all, or not what would be expected of two steps. What is my trouble?—Edward L. Richardson, Coffeyville, Kan.; P. O. Box 267.

We refer you to the diagram in this department in answer to a query on the Flewelling circuit. You will note that it is two stages, but when you construct it just end your construction at the first jack leading to the transformer. The variometer you state you have is not necessary in this circuit, as the only apparatus you need is a transformer, socket, bulb, rheostat and panel. Of course, extra B batteries are necessary.

You will not notice any appreciable increase in the strength of the signals when you use radio frequency, but a noticeable increase in the clearness of signals will be noted if you have the circuit hooked up properly. The use of radio frequency increases the distance, but not the strength so much. It clears up the signals appreciably.

* * *

1. *Kindly publish hook-up for the following: Variocoupler, condensers, W-D 11 tube, variable grid leak, etc.*

2. *Does it matter which lead from the rotor goes to the plate?*

3. *In the hook-up where could I place a 23-plate condenser to the best advantage?—Earle Vanderlick, 1920 West Broadway, Minneapolis, Minn.*

1. We refer you to the hook-up published on page 20 of RADIO WORLD for March 17, 1923. The two condensers are used in the places marked, while the one across the rotor is optional, meaning that it can be used if found convenient.

2. Yes. The leads of the rotor will interfere with the working of the circuit if they are not connected right. This can be determined by switching them and finding which works.

3. The two condensers are marked.

* * *

Kindly tell me of a method of decreasing the clicking interference caused by a pole-changer located in a telephone office near my receiver. Have tried using condensers. —Henry M. Willard, New Berlin, N. Y.

If you refer to RADIO WORLD for January 20, 1923, you will find the method of eliminating interference described on page 20 in answer to an inquiry very much the same as yours.

* * *

Have constructed a radio outfit for use on the dash of my Hudson speedster, but have had trouble to get a good ground. Am using a five-foot loop, but cannot figure out how I can make a ground on the car.—Harry Gill, 405 Searvin avenue, Bridgeport, Conn.

When you are using a loop antenna you do not need a ground. That is one of the advantages of the loop antenna. It is connected directly across the circuit in place of the secondary of the tuner, and the tuning is done by means of a condenser in parallel with it. Don't try to get a ground, as it is not necessary. We advise using at least one step of radio frequency with this type of receiver, especially as you intend to use it on a car.

* * *

1. *Can slate be used successfully for radio panels?*

2. *Would sections cut from a phonograph record be of use for a panel?*

3. *What plate voltage should be used on a detector and two-stage amplifier set using W-D 11 tubes?*

4. *Can more than two stages of audio frequency be used successfully without the use of power tubes?—Olney Wilbin, Hartland, Me.*

1. Slate can be used as a panel, but it is not advisable because, as a rule, a vein runs through the slate which partially destroys its insulating qualities; also, it is hard to work, and is not as good as even poor-grade, hard rubber. Better use the regular paneling and save trouble.

2. You can use the composition of which records are made if you wish. It makes a good insulator for panels, but is extremely brittle. Care has to be taken when drilling and working it.

3. In using the W-D 11 as detector 22½ volts is sufficient, but when used as an amplifier it works best with 45. You can, however, place 60 volts on the plates of the amplifier without harming them.

4. You can use more than two stages of audio frequency without the use of power tubes; but if you do you will be bothered with excessive tube noises, which always are noticed when more than two stages of audio frequency are used.

* * *

In regard to the hook-up published in RADIO WORLD *for February 17, 1923, by G. W. May: Can a W-D 11 tube be used with this set? What parts are necessary for the construction of this set?—Edward A. Futter, 21 Hunter street, Newark, N. J.*

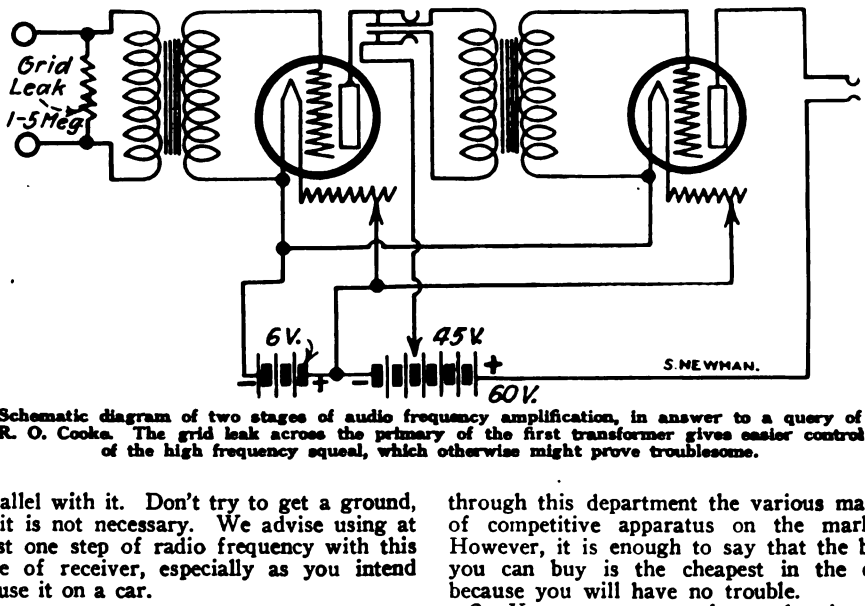
This hook-up can be used successfully with a W-D 11. The parts necessary for the construction of this set are: A honeycomb coil mounting, variometer, rheostat, socket, tube, grid leak and condenser, A batteries, B batteries, .001 variable condenser, and the necessary wire for connections. The diagram in the issue you mention is the only one that can be had, and it can be made no simpler.

* * *

1. *In the circuits published in the February 24 and March 3 issues of* RADIO WORLD*, what radio frequency and audio frequency transformers can be used?*

2. *Will the U. V. 201A function in these circuits?—A. B. Morrison, 119 West 8th street, Bayonne, N. J.*

1. We cannot discuss or recommend through this department the various makes of competitive apparatus on the market. However, it is enough to say that the best you can buy is the cheapest in the end because you will have no trouble.



Schematic diagram of two stages of audio frequency amplification, in answer to a query of R. O. Cooke. The grid leak across the primary of the first transformer gives easier control of the high frequency squeal, which otherwise might prove troublesome.

2. Yes, you can use these tubes in this circuit.

* * *

1. *Where can I obtain reflex circuits embodying both crystal and tube detectors?*

2. *Are special transformers needed with W-D 11 tubes?—E. H. Guy, 4943 Monticello avenue, Chicago, Ill.*

1. If you will refer to RADIO WORLD for February 24, 1923, and March 3, 1923, you will find the information you want under the heading "Reflex Circuits," by W. S. Thompson.

2. No special transformer is needed, but a transformer which has a high ratio works best with these tubes. There are several on the market.

* * *

Kindly furnish me with a two-stage audio-frequency hook-up in accordance with the information in this column last week, using a grid leak across the primary of the first transformer in the Flewelling circuit.—R. O. Cooke, 2256 Broadway, New Haven, Conn.

The hook-up you request is published herewith.

Magnavox *prices* are the result of Magnavox *quality*

IN the long run, the price of the really successful and satisfactory product is set by the *purchaser*—not by the *maker* or the *dealer*.

Because when the manufacturer and dealer charge too much for a product, they destroy its market; and when they charge too little they destroy its quality—which results in the same thing—loss of market.

Magnavox Radio products are of the highest quality—and their prices bring them within reach of every serious radio user.

R2 Magnavox Radio
(With 18-inch horn)

This instrument is intended for those who wish the utmost in amplifying power; for clubs, hotels, dance halls, large audiences, etc. It requires only .6 of an ampere for the field.
Price $60.00

R3 Magnavox Radio
(With 14-inch horn)
As illustrated

The ideal instrument for use in homes, offices, amateur stations, etc. Same in principle and construction as Type R-2.
Price $35.00

Magnavox Power Amplifier
As illustrated

For use with the Magnavox Radio and insures getting the largest possible power input.

Model C, 2-stage, $55.00
Model C, 3-stage, $75.00

Magnavox Radio can be used with any receiving set of good quality. Ask your dealer to demonstrate it *with* the Magnavox Power Amplifier, as illustrated. This combination produces the most satisfactory results.

What matters bad weather when Radio entertains?

RADIO'S "every-hour-every-where" broadcast schedule is the most stupendous organization of the means of entertainment the world has ever witnessed.

So responsive have people been to the opportunity of enjoying these programs at their best that Magnavox equipment has become synonymous with the full enjoyment of radio music and speech for an ever-greater circle of satisfied users.

Magnavox Products can be had from good dealers everywhere. Our interesting new booklet will be sent on request.

Factors Which Affect Selectivity

By W. S. Thompson, E. E.

WITH broadcasting conditions as they are today, a receiving set that is very selective is of the utmost value and is practically a necessity. By definition, selectivity is the ability to tune in one of the many transmitting stations and tune out all others. This is very difficult when two or more transmitting stations are sending at exactly the same wave length and are equally distant from the receiver. However, the broadcasting stations of today usually differ in wave length from two to fifty meters, so by constructing the receiving set along the lines of best design it will acquire the characteristic called selectivity.

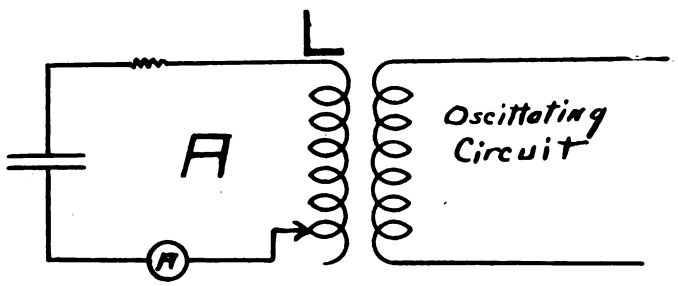

Fig. 1. Illustration depicting tuned primary circuit of a simple set, with ammeter in circuit to show current flow. This is the simplest type of oscillatory circuit.

In order to show the effect of different factors upon selectivity, the author has performed the experiments discussed below and has given reproductions of the graphs plotted from the data taken during these experiments. The resonance curves given are curves in which distances above the horizontal axis represent certain amounts of current, and distances to the right of the vertical axis represent wave lengths to which the circuit in question is tuned. Thus, by plotting change of current against change of inductance, the curves show at a glance how a given change of inductance will affect the current.

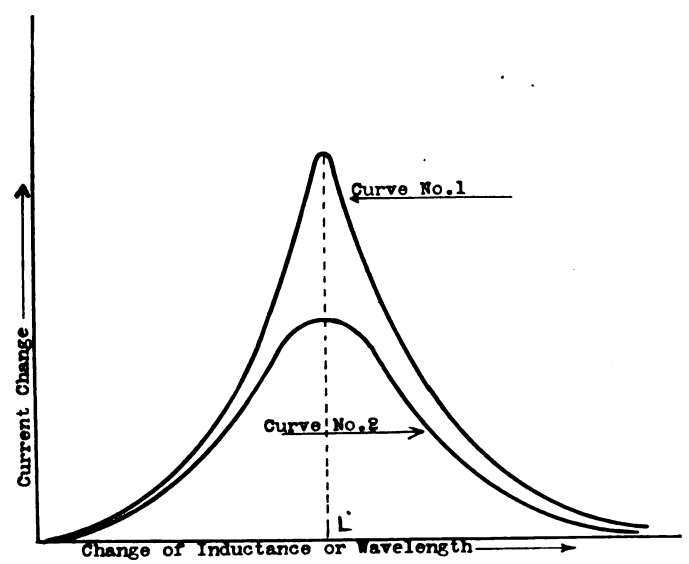

Fig. 2. Curve plotted to show current change as inductance is changed in the circuit.

One of the most important factors in making a set selective is to have a minimum resistance in the circuits making up the set. This is accomplished by using a large size copper wire for connecting all apparatus and by carefully soldering all connections. Any loose connections and any small size wire introduces resistance, the effect of which will be shown. In order to illustrate the effect of resistance on the selectivity of tuning we will take the case of an antenna circuit consisting of capacitance and inductance. Fig. 1 is the equivalent circuit of a tuned primary circuit of a simple set with an ammeter introduced to show the current flow in this part of the apparatus, which is coupled to an oscillating circuit as shown. The oscillations in this generator circuit are of a definite wave length corresponding to a transmitting station. As the value of the inductance L is changed from minimum to maximum the deflection of the ammeter rises to a maximum value and then decreases to a low value as shown by the resonance curve 1 in Fig. 2. When the inductance L is at a value L, the current flow is a maximum so we say that circuit "A" is tuned to the same wave length as the oscillating circuit. Curve 1 has a sharp peak at the top which shows if we either increase or decrease the value of the inductance L a very small amount

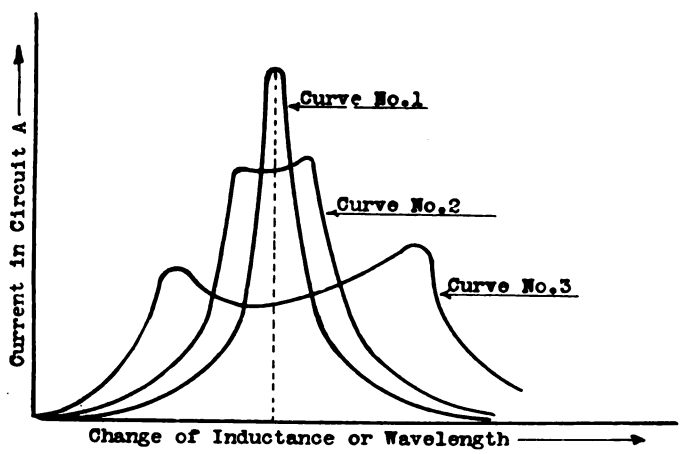

Fig. 3. Three curves plotted for three different values of coupling, showing the difference in the peak of the wave when close, medium, or loose coupling is used.

the current will fall to a much lower value. This means that if there is a sharp peak on the resonance curve of a circuit and there was a telephone receiver circuit in place of the ammeter, that a small change of the inductance would cause the induced current to fall to such a low value that there would be no response in the phones, showing that the response to a given transmitter is only on a very small portion of the variable inductance and the circuit is said to be selective. Now suppose that there was a high resistance in this circuit and again the circuit was tuned as before. The value of current shown by the ammeter would follow the resonance Curve 2 of Fig. 2. From this curve we can see that a small change of the inductance L would not affect the value of the current to any great extent. That is, if there was a telephone receiver circuit in place of the ammeter, the intensity of the sound would not change for a small change of L hence the curve shows that the addition of resistance broadens the tuning to a very marked extent because a very large change of L would be necessary to tune out any transmitting station. This discussion of resistance broadening tuning applies to all circuits of every type of receiving set, so the importance of large bus-bar connec-

(*Continued on following page*)

(*Continued from preceding page*)

tions and soldering cannot be too strongly emphasized.

Another very important factor affecting selectivity is the coupling between circuits. In this discussion Fig. 1 will represent a secondary circuit "A" coupled to an oscillating antenna circuit as shown. The ammeter will take the place of a crystal and telephone receivers in order to show exactly the values of current induced in this circuit by the coupled primary. The procedure in conducting this test was to set the coupling as tight as possible and then tune circuit "A" taking values of current for different settings of the inductance "L" as in the preceding experiment. This procedure was repeated for three different values of coupling; that is, for very close, medium and loose coupling, giving the three curves shown in Fig. 3. Curve 1 represents the resonance curve with loose coupling, showing the sharp peak which is the characteristic of a very selective circuit. Curve 2 is the resonance curve for the close coupling and has a rather flat top showing that with this coupling a considerable change of inductance L would be necessary to change the intensity of signals. Curve 3, that of the very close coupling, has two distinct peaks, showing that the circuit will respond to the same transmitter at two different settings of the inductance. This would be a very bad state of affairs in a receiving set, for it would be almost impossible to separate two stations if they were sending on wave lengths nearly the same. From these curves the conclusion must be drawn that by loosely coupling the circuits of a receiving set, selectivity will be gained. However, advocates of closely coupled circuits, claim that loosely coupled circuits always greatly reduce the signal strength. The fallacy of this argument will be shown by the following procedure: Circuit "A" was tuned to give maximum response as shown by the ammeter and then the coil "L" was removed far enough away from the corresponding coil of the oscillating circuit until there was no response in the circuit "A." Then coil "L" was moved toward the oscillating circuit coil until the coupling was very close. The current in circuit "A" as read from the ammeter, followed the curve in Fig. 4, showing that the current increased as the coupling was tightened, until a certain degree of coupling was reached after which any further tightening of the coupling decreased the response. This clearly shows that very close coupling does not give the maximum signal strength. The explanation of this phenomenon is that when the coupling is very close the secondary circuit gives back part of its induced energy to the primary, hence weakening the current in the secondary.

Fig. 4 also shows that if the coupling is loosened beyond the point which gives maximum response, the intensity of the signal strength will decrease. This property may be made use of in a very interesting way. By referring to Fig. 5, the solid lines represent the resonance curves of Circuit "A," Fig. 1, for two different wave lengths, corresponding to two different transmitting stations sending at the same time. The line "I" represents the value of current necessary to give a response in telephone receivers, and as these two resonance curves overlap above this value of current, there will be interference between these two stations. That is, both stations will cause a response in the receivers at the same time. However, if we loosen the coupling between the two circuits, until the response in the secondary circuit is less, the two dotted resonance curves will then represent the response to these two stations. As the two dotted curves do not overlap above the critical current of the telephone receivers, there will be no interference between these two stations. As the two dotted curves do not overlap above the critical current of the telephone receivers, there will be no interference between these two stations, so that one and only one will be heard.

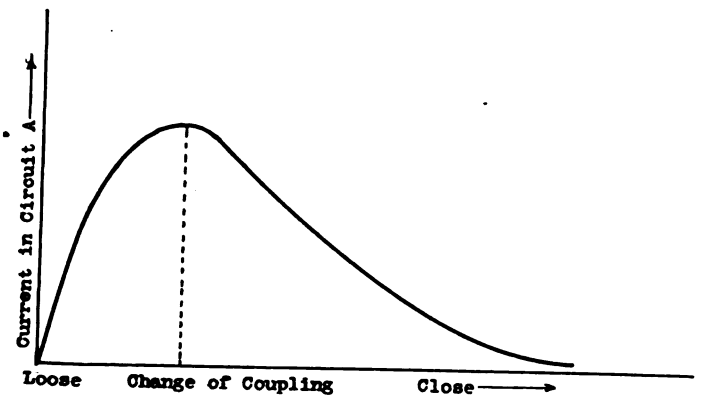

Fig. 4. Showing how, if the coupling is loosened beyond a certain point, the response of the signal suddenly decreases.

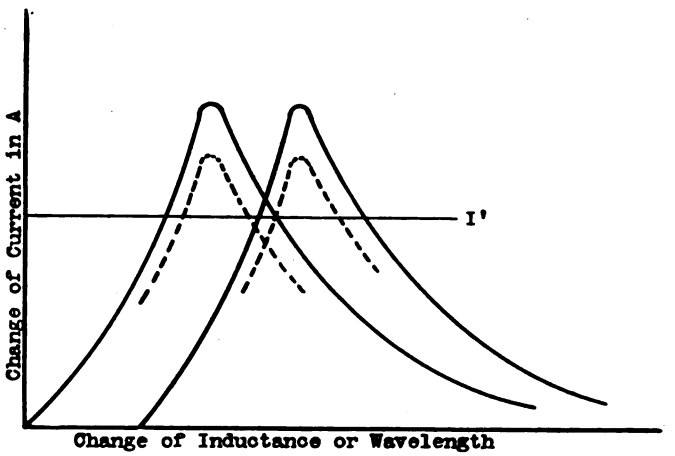

Fig. 5. Resonance curves representing two different waves corresponding to different stations sending at one time.

Seven New Broadcasters on 360 Meters

THE supplemental list of limited commercial broadcasting stations licensed during the week ending March 17 follows:

Call	Station	Power
KQP	Apple City Radio Club, Hood River, Oregon	10 watts
KFHB	Boardwell, P. L., Hood River, Oregon	10 watts
KFFV	Graceland College, Lamoni, Iowa	250 watts
KFDZ	Iverson, Harry O., Minneapolis, Minn.	5 watts
KDZQ	Pyle & Nichols, Denver Colorado	100 watts
WRAH	Read, Stanley N., Providence, R. I.	10 watts
KFDY	South Dakota State College of Agri. & Mech. Arts, Brookings, S. D.	100 watts

A Year of Radio Progress

March, 1922, to March, 1923

March 29, 1922. First Issue of RADIO WORLD.

Second Annual Radio Show

Armstrong's super-regenerative and super-heterodyne circuits perfected. A marvelous step in the progress of super-sensitive receivers.

Photographs sent by radio from Italy to the United States. The first invention of its kind to send pictures through the ether.

KDKA First radio broadcasting station to be heard in Iquique, Chile, South America, and the first broadcasting station to establish a record distance for long distance program broadcasting.

Marconi makes a flying visit to the United States to confer with Steinmetz and other electrical and radio experts.

Dr. Irving Languir perfects a 20 kilowatt vacuum tube, the most powerful ever made.

The 1½ volt tube perfected.

First opera broadcast over the country.

Amateurs of United States and France establish communication on low waves and low power, breaking all records for distance over low wave lengths.

Dr. Lee de Forest confers with foreign scientists and perfects talking motion pictures.

World Series baseball games broadcast for the first time.

Football games broadcast over land wires and rebroadcast over radio, combing the two successfully for the first time.

National Radio Week proclaimed and celebrated—the most successful public week ever held in behalf of an industry. Big boom in the radio field.

First successful two-way communication—the annual meeting of the Westinghouse stockholders in Chicago and New York 1,000 miles apart. Perfect co-ordination was maintained through the agency of two-way communication via radio.

The White Bill, for the control of radio passed by the House and killed in the Senate.

Broadcasting stations heard and reported in both England and France, breaking all previous records for continuous program reception and transmission.

Several popular plays broadcast directly from the stage of the theatres in which they were given.

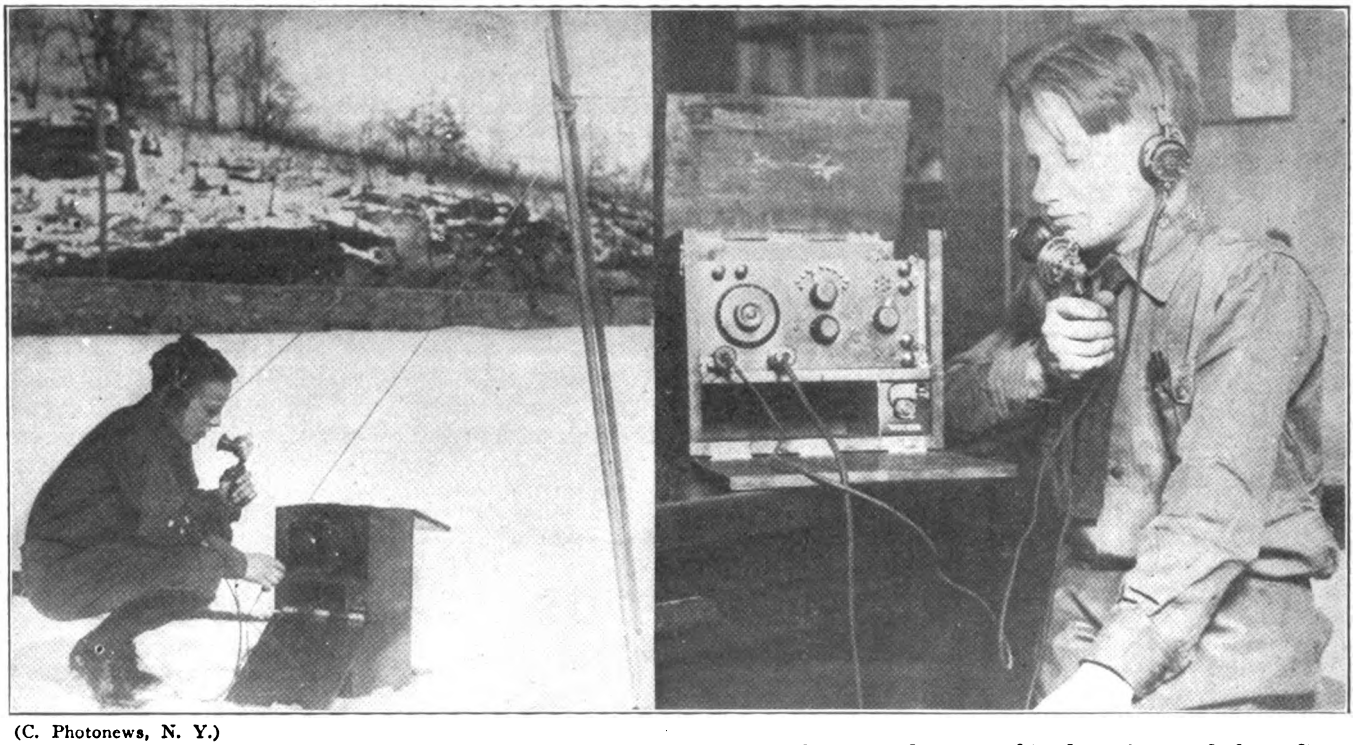
Third Annual Convention of the Second Radio District. A wonderful success.

General Harbord assumes presidency of the Radio Corporation of America.

Station at Rocky Point, Long Island, which will make the United States the center of all radio communication, brought to a point of perfection. Marks a marvelous undertaking in radio.

March, 1923, RADIO WORLD begins its second year of useful service.

Boy Scouts Active in Radio



(C. Photonews, N. Y.)

Little has been said or written about the Boy Scouts' activities in the field of radio. Nevertheless, ever since the days of 5 kw Coffins and crude galena detectors constructed out of odd pieces of material found lying around, the Boy Scouts of America have always been interested in the science.

Lately much notice has been given to the activities of the Scouts when camping out, and the illustration above shows one of the portable outfits that was built by Troop 501, of New York City.

The outfit pictured is a combined receiver and short distance transmitter, working on the same tube. It was built by the members of the troop and can be used either as a receiver or transmitter by plugging in either the receivers or the microphone. One of the illustrations shows a near view of the set, while the other depicts the set in actual operation while out on a hike, using a portable antenna which is part of the outfit. The set is self-contained, being operated on batteries carried in a separate compartment, which fits under the set proper.

Radio Regulation in Cuba

PENDING the passage of a law to cover the use of radio telegraph in Cuba a presidential decree has been issued defining the various classes of non-governmental radio stations and prescribing certain general rules for their operation, says Acting Commercial Attaché P. L. Edwards in a report to the Department of Commerce. Up to the present time there has been no law or regulation covering the construction or operation of radio stations in Cuba.

Under the decree non-governmental radio stations are divided into five classes—A, B, C, D and E—to each of which is assigned a wave length and a maximum power. No sets of any of these classes will be used for commercial purposes. Classification is as follows:

Class	Wave length (meters)	Maximum power (kilowatts)
A*—Amateurs	200	½
B —Educational Institutions, experimenters.	225-275	½
C —Colleges, state institutions in general	300-360	½
D —State institutions only	400	½ to 1
E —Meteorological stations only	485	½ to 1

*All receiving sets are rated Class A, regardless of type or size.

All owners of stations coming within any of these five classes must register with the Director General of Communication before a stated date. After that date no station may be used unless the proper permit has been issued by the office mentioned. The permits are for a term of one year in the case of classes A, B and C, and for five years in the other two classes. Applicants must pass an elementary examination, but it is not believed that this requirement will in any way hamper the issuance of licenses. The decree further provides that the government may, under specified circumstances, require transmitting stations of any of the five classes to cease operation without claiming indemnity from the government. Transmitting stations of any class are made subject to the regulations of the International Radio Convention, signed in London in 1912. The decree also prohibits the transmitting of the international distress call, S.O.S., either as a special signal or in the course of any general text. Penalties are provided for the disclosure of any public or government message intercepted by any station. Only apparatus capable of transmitting a continuous wave may be used.

Transmission Poor

Physics Professor—"Does any one know anything about violet rays?"

Stude—"I do, but I promised not to give her away."—*Chaparral.*

RADIO BROADCASTING MAP

FOR the benefit of those interested in Radio and those who are becoming interested, Rand McNally & Company have prepared a publication containing a wealth of information of greatest value. It shows in the most comprehensive way, the location of the broadcasting stations, gives their classification, the call letters, wave lengths, ownership, etc., of each

Everyone who wishes to get the maximum pleasure and enjoyment from Radio should have a Rand McNally Radio Map of United States. It is complete, accurate and up-to-date.

The Rand McNally Radio Map of United States is 36x50 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover

Radio World Begins Volume III

WITH this issue RADIO WORLD begins its second year of useful service.

It is doubtful if, in the history of the publishing business, an empty niche has been occupied with such satisfaction to readers, advertisers and the publishers as in this instance.

Our readers have demonstrated positively and concretely that they get what they want in our columns. Our volume of sales from newsstands is surprising even to us.

The increase of business secured by our advertisers has been decidedly profitable to them—and they have told us so.

RADIO WORLD will continue to give, week by week, the latest in the rapidly expanding radio field. The news will be in our columns first, and the technical development of the field will be noted by experts as it occurs.

We thank our friends for their support in our infancy, and will put forth every effort to continue to deserve it in our expanding youth.

RADIO AGENTS

Agents and small dealers wanted in every city and town to sell standard lines of radio apparatus on commission basis. Liberal compensation.

How Radio Advertising Can Be Made to Pay

By Irving Bresalier

THOUGH radio as a science and art is a comparatively new world-wide development, touching the interests of men and women in every walk of life, the foremost consideration that should be kept in mind by those who are shouldering the responsibility of radio merchandising today is that the basic principles of marketing, no matter what industry is considered, are fundamental.

As a problem of distribution radio should be considered from no different viewpoint than any other new product which might be introduced in any older industry.

Because advertising is strongly linked with selling effort of every kind, and because this indispensable aid to distribution is now proving to be one of the most potent factors in radio merchandising, the application of our best thought and attention to this important subject will meet with due reward.

How can adverising be made to pay? No doubt every advertiser has repeatedly asked himself this question.

To begin with, advertising is not a gamble. Skilfully handled, advertising can be turned into an investment that will pay for itself over and over again in sales made and good-will gained.

Let us consider what elements or factors are fundamental to the success of an advertising campaign, with particular reference to radio.

First and foremost is the necessity of a *definite plan.* Is it desired to establish jobbers or dealers, or are direct sales to consumers sought? A definite decision in this respect is vital, as copy directed to dealers is essentially different from an appeal to consumers. Such considerations as discount schedules, exclusive agencies, etc., should be determined in a specific sales policy even before advertising is started.

In launching an advertising campaign the guiding principle should be consistent effort, as opposed to piece-meal publicity or spasmodic splurges. The constant dripping of water has been known to wear away a rock. The cumulative effect of consistent advertising will in time accomplish its purpose as effectively. In this connection it would be well to remember that "keeping everlastingly at it brings success."

Second: Efficient use must be made of advertising space. Mere capacity to buy large space in a publication is not an assurance of profitable results. The copy of an advertisement must be convincing and its presentation attractive. To attract the attention of the reader and convert his interest to buying desire calls for a thorough knowledge of advertising principles. The responsibility of filling advertising space should therefore be delegated only to one trained in publicity methods. Advertising has developed into a science—it has long ago passed out of the realm when pretty pictures and clever sayings could be depended upon to put across the sales message.

Third: Most advertisers are lulled into a sense of satisfaction upon the receipt of mere inquiries, failing to realize that, at this point, the selling task has only begun. Because of ineffective follow-up of inquiries through attractive and attention-compelling circulars, booklets, catalogues, etc., advertisers are losing their greatest opportunity to turn passing interest into profitable sales. In many cases failure to make advertising pay may be attributed rather to the indifference of the advertiser in the matter of proper follow-up than to the inefficacy of publication advertising as a sales-producing medium.

The writer of this article, upon asking a radio advertiser what results his space was producing, received the boastful reply: "Oh, we are getting a raft of inquiries." Upon asking to see the printed matter for following up these inquiries the writer was informed: "Why, we have no printed matter. All we do is to quote prices on our regular letterhead."

Think of the absurdity of the method of this advertiser! After investing a goodly sum for space practically no subsequent effort is made to capitalize the results. Of course the periodical used by this advertiser will be blamed if sufficient sales are not made to cover the advertising expenditure.

In contemplating advertising one must realize that results cannot be obtained by pursuing a hit-or-miss policy. Permanent, profitable returns can be gained only by adhering to the common-sense principles which are at the basis of all successful advertising. These, summarized, are a pre-determined, specific plan, continuity of effort and effective follow-up of inquiries. There is no reason why the spectacular results achieved through the advertising of products in other lines cannot be realized in the radio field.

Radio Renders Aid in Storm

WHEN a sleet storm which recently raged through the Middle West disabled telegraph wires, broadcasting station KYW, of the Westinghouse Electric & Manufacturing Company, at Chicago, aided news agencies, railroads and brokerage concerns in relieving the ensuing distress.

A Help for Reflex Set Builders

Manufactured by Jaynxon Laboratory, 57 Dey Street, New York City

A SYNTHETIC crystal recently brought out by the Jaynxon Laboratory will evidently meet with a great demand by the makers of reflex sets, as well as convert quite a few of the tube users back to crystals for a while. It is a gray composition, resembling lava in appearance. It is equally sensitive over a large surface, and is therefore much to be desired by those who intend to utilize crystal detection in the use of radio frequency or reflex sets. The name of the crystal itself is Reflex, and it therefore suggests that use for the crystal. The fact that it is so extremely sensitive over such a large surface, and under test is practically "unknockoutable," should make it very popular.

The Filkostat Assists Fine Tuning

MR. S. R. HIPPLE, well known for his inventions in the field of electric current control, has devised an instrument called the "Filkostat," designed to utilize the great tuning possibilities of the vacuum tube itself. The Filkostat permits perfect regulation of filament heat, an essential to perfect tuning. The extreme degree of fineness in increase and decrease of electronic flow by infinitesimal gradations makes the Filkostat control ideal and adds to the life of the tube.

This new instrument is claimed to be non-microphonic, absolutely silent and free from all noises, due to perfection of design and ample internal contact. It has other valuable advantages of great interest to amateur radio-set builders, as well as manufacturers. The DX Instrument Company, Harrisburg, Pa., are manufacturing the Filkostat, and its international distribution is in the hands of the Radio Stores Corporation, New York City.

A Compelling Window Display for Radio Dealers

By Arthur G. Shirt

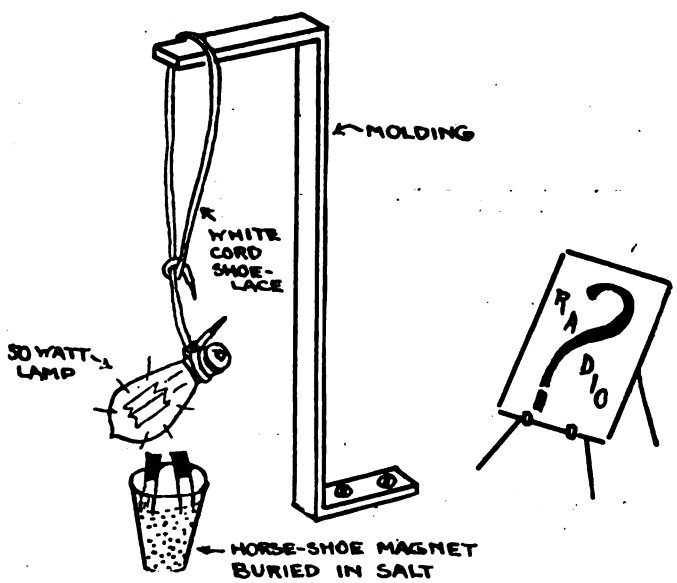
A NOVEL and interest-compelling window device has been used recently by Doughty & Welch, electrical contractors, Fall River, Mass., to call attention to their side-line of radio apparatus. In the very center of their display window, and isolated from the other exhibits, stood an angle stand of wood molding, and from the molding hung a 50-watt electric lamp. Although there were no visible connections to the light it was burning very brightly. Underneath the lamp was a tumbler full of salt, while buried in the salt with its poles turned toward the light was a horse-shoe magnet. How the electricity got to the lamp was a deep mystery, for it was hung from the standard, not by wires, but by a white cord shoe-lace.

The interest taken by the public in this mysterious device more than repaid the trouble taken in making it up. While the crowds outside the window wondered Messrs. Doughty and Welch brought their radio message before them by placing a card in the window with a big red question mark prominently displayed. On the card was printed also the word *"Radio."*

"Well, it might be," thought the throng outside, "and then again it might not." Probably one out of every twenty went inside the store to find out, and while they were in there they incidentally were introduced to a high-grade line of radio goods. Curiosity may have killed the cat, but it had no damaging effect on the trade of Doughty & Welch.

The secret of the whole device, of course, lies in the clever concealment of the wires leading to the lamp. They come along the floor of the window under the plush or velvet covering and enter the molding from the bottom. They are run up the molding, and both come out into the shoe-lace, so that, although the shoe-lace looks as if it were casually thrown over the standard, it is really fastened there by the wires. One wire goes down to the lamp through one side of the shoe-lace and is soldered on to the shell of the 50-watt lamp. The other wire travels down the other side of the shoe-lace, goes through a hole drilled in the shell and is soldered to the center contact. All this, of course, is carefully done and also carefully insulated so as to prevent short-circuiting. The connections to the base of the lamp are concealed by the wrappings of the shoe-lace around the shell.

The tumbler of salt and the magnet have nothing to do with the device at all. They are placed in a position under the lamp to increase the mystery and possibly to divert the scrutiny of the public from the true explanation. The sign with the big question mark suggests that radio might be responsible, and so calls attention in a novel way to the remainder of the window display, which, of course, is made up of radio apparatus of popular appeal.



Radio Dealer's Window Display Which Is Sure to Attract Attention

New Radio Firms

(*The new firms and corporations mentioned in these columns can be reached directly or by communicating with the attorneys, whose addreses are given whenever possible.*)

Thermoflasher Corp., Syracuse, N. Y., electrical novelties, $15,000; H. N. Frances, F. L. Robbins, C. F. McKay. (Attorneys, Higbie & Malpass, Syracuse.)

Pittsburg Generator Co., McKeesport, Pa., increase of capital from $300,000 to $5,000,000.

Radio Reynolds, New York City, $10,000; B. Reynolds, M. Klein, A. Werner. (Attorney, J. Klein, 152 West 42d St.)

Park Place Radio Electric Company, New York City, $20,000; S. S. Goldstein, M. Heberman, P. R. Steigleman. (Attorneys, Janover & Janover, 30 Church Street.)

Radio Insulate Corp., New York City, transmitting apparatus, $200,000. (U. S. Corporation Co.)

Simplex Radio Corp. and Electrical Supply Co., stocks and bonds, $100,000; Alfonso Berrico, Attilio Derrigo, Robert I. Torone, Boston, Mass. (Corporation Service Co.)

New Era Electric Corp., New York City, $1,500,000. (U. S. Corporation Co.)

Utica Battery and Electric Co., Utica, N. Y., $25,000; H. Rosenmeyer, R. H. Vaughan, H. Meehan. (Attorney, F. J. McEwen, 70 Broadway.)

Nodens, Brooklyn, N. Y., make electric supplies, $25,000; A. and V. A. Noden. (Attorney, B. H. Noden, 115 Broadway, New York City.)

Hall Electric Corp., Kenmore, Erie County, N. Y., $10,000; C. E. and P. B. and R. V. Hall. (Attorneys, Wilcox & Van Allen, Buffalo, N. Y.)

Radio Construction Co., Delaware, 500 shares preferred stock, $100 each; 7,000 common, no par value; rep., H. H. West, 15 West 44th St., New York City.

New Records of The DX Nite Owls

Working Overtime for These

From J. E. Bradley, Justin, Tex.

I WANT to submit to the DX Nite Owls my February report. Worked 107 hours 24 minutes; total stations, 449. Now this doesn't count any station within 100 miles. Days worked, 26 (missed two). 105 different stations, 102 in U. S. A., in 29 different states, 1 in Canada and 1 in Cuba, viz.: WCM, WOAI, WLAL, KLZ, KFAF, WDAF, WHB, KSD, WOS, WHAS, WIAR, WGM, WSB, WDAJ, WOI, WOC, KHJ, WAAZ, WWJ, WDAP, WEAY, WKY, WJAN, WFAV, WFAT, KNJ, WMAB, WEAZ, WPAC, WOAL, WCAH, WKAL, WLAG, WIAO, WBL, WCX, KYW, WLW, KFI, WLK, PWX, WTAW, WOAA, KWH, WHA, WOAK, WOAZ, WHAN, KOB, 5YQ, WMAJ, WAAP, WGY, WMC, WSY, KDKA, WCAZ, WRAM, WKAC, KZN, WOAN, WWAX, WMAT, WJAP, WGV, KDZQ, WJAX, WCAL, WJD, KGW, WQAQ, KFDL, 9DHB, 5ADO, WLAZ, WCAR, WGF, WPAH, WIAS, WMAV, KDPT, WPAS, WCAJ, KFFQ, KDYS, WMAQ, WMAK, KFAP, WPAK, KFHJ, WOR, WCAZ, WLAS, WJZ, WCAS, WAAN, KFBK, WGAT, KUO, WUD, WBT, WPE, WJAQ, WHAB, CHBC.

I would like to hear from some DX'ers with two-tube sets. Mine is a two-tube (WD-11) short wave regenerative, consisting of two-tubes and sockets, Grid leak and condenser, phone condenser, two rheostats, one variometer, two condensers and one transformer. I thank you for devoting part of your good magazine to us DX'ers.

* * *

THE Editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

Cuba, Hawaii, Porto Rica and ships. I have a two step and Magnavox. I have a little crystal set, and have heard KDKA, WJS, WWJ, WOC, WHAS, and February 21 I heard a station in Kansas during WPAL. I only use my crystal set when I am getting my battery charged.

* * *

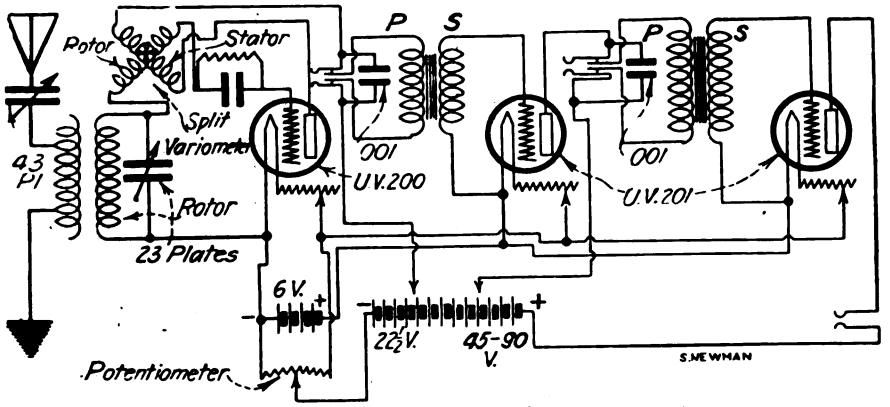
A New One from a DX'r to the Bunch!

From Earl E. Gibbins, Room 217, Dexter Bldg., Springfield, Mass.

ENCLOSED you will find a simple but very effective circuit with which I am receiving the United States, Canada, Cuba, and all the others worth mentioning.

After reading your magazine regularly and noticing the DX results I feel that my circuit is worth of mention and will give the Nite Owls something to shoot at, even if it should pass over their heads.

It is an original idea of my own, after plenty of experimental work, and I am sure that it is the equal of any if not superior to most of them for bringing the DX.



Circuit used by Mr. Earl E. Gibbins, and one that will suggest some improvements to you DXrs. Note the fact that he uses a split variometer, which, although not a new idea, is original, and that is what counts.

I have varied the original circuit and use a split variometer which I believe makes it different from any other circuit that has heretofore been published. I will be glad to furnish any additional data upon request, if a stamped self-addressed envelope is enclosed for reply.

If any "Nite Owls" can suggest any improvements on this, I will be glad to "get together" with them.

* * *

Uses Home-Made Spider Web

From Joe Colborn, Memphis, Tenn.

I AM very much interested in the "DX Nite Owls" as published in RADIO WORLD. I am sending in my record:

WDAJ, WHB, KDKA, WBAP, WSB, WLAG, WLW, KSD, WOC, WAAL, WJAK, WFAA, WWJ, WDAF, WGY, WCX, WBT, KFAF, WHAS, WOAI, WOR, PWX.

I am using home-made, spider web coils and WD-11 tube without amplification.

* * *

From a Young Buckeye

From Ralph Mallory, Columbus, Ohio.

I HAVE been reading your DX Nite Owls' records and decided to send mine in. I am thirteen years old. On February 15 about one hour and fifteen minutes. The stations are as follows: KDKA, WIAO, WOR, WOO, WHA, WOC, WDAP, WIAR, WGY, WMAQ, and WDAJ through WEAO. I have heard stations throughout the country, including Canada,

Hot Dawg! Let's Step!

From C. W. Hallowell, Susanville, Calif.

The writer was discussing the article on Radio Golf which appeared in your magazine under date of Feb. 3d, with the "Old Man" of our local radio colony here, Mr. H. B. Pearce, who stated that he was of the opinion that this record could be broken and on the evening of Feb. 13th proceeded to do so.

We are, therefore, submitting attached a list of the stations which he received and practically in the order in which they came in. Considering that all stations East of California have to be brought through some of the powerful California stations which are on early in the evening, we were at a serious disadvantage compared with persons situated in the Mississippi Valley or even on the Atlantic coast, and under the circumstances feel that a record of about 7,000 miles per hour will give the boys something to shoot at for a few days.

The set which was used was a British Radio-Frequency Tuned-Plate Reactance Type Receiver which was built by Mr. Pearce, Mr. George Harrison and the writer.

5:00 to 10:25 P. M. Pacific standard time. WGY, Schenectady, N. Y., 2,502 miles; WJZ, Newark, N. J., 2,516; WHAS, Louisville, Ky., 1,941; WAAS, Decatur, Ga., 1,950; WCOE, Pittsburgh, Pa., 2,221; KGG, Portland, Ore., 381; KUO, San Francisco, Calif., 226; KWH, Los Angeles, Calif., 474; KMO, Tacoma, Wash., 503; WWJ, Detroit, Mich., 2,027; KFBK, Sacramento, Calif., 137; KDYL, Salt Lake City, Utah, 482; WHA, Madison, Wis., 1,680; KHJ, Los Angeles, Calif., 474; KZM, Oakland, Calif., 216; KZN, Salt Lake City, Utah, 482; KLZ, Denver, Colo., 863; KLX, Oakland, Calif., 216; KFV, Yakima, Wash., 446; KFAF, Denver, Colo., 863; WBAY, New York, N. Y., 2,530; WBAP, Fort Worth, Texas, 1,445; WCX, Detroit, Mich., 2,027; CFCN, Calgary, Canada, 866; KJS, Los Angeles, Calif., 474; WDAP, Chicago, Ill., 1,783; KDPT, San Diego, Calif., 589; KMJ, Fresno, Calif., 309; KFAN, Moscow, Idaho, 489; KGB, Tacoma, Wash., 503; KFEL, Denver, Colo., 863; KWG, Stockton, Calif., 180; KPO, San Francisco, Calif., 226; WLW, Cincinnati, Ohio, 1,991; KGY, Lacey, Wash., 475; KFAT, Eugene, Ore., 180; KFHJ, Santa Barbara, Calif., 350; WFAA, Dallas, Texas, 1,481; WDAF, Kansas City, Mo., 1,445 miles. Total, 38,806 miles.

* * *

Come Along, Owls!

From Fred Temby, Bloomingdale, N. J.

FOLLOWING are the stations I received using a single-circuit, feed-back set and one W-D 11 tube:

2XY (testing), WJZ, WOR, WSB, WBS, WRW, WOI, WIP, WFI, WLW, WBZ, KOP, KYW, WMH, WGI, WGY, WRK, WWJ, WQC, WBAY, WCAN, WNAC, WBAP, WKAA, KDKA, WCAE, WAAM, WHAS, WBAN, WGAM, WGM, WST, WBAZ, WAAP, WHAZ, WGF, WOO, WCZ, WMAM, WMAQ, WAAW, WMZ, WAID, WLAC, WJAX, WWI, WHAM, KSD, WBT, CHYC, WBAP, PWX.

These stations came in clear, and I am sure of every one. I received several of which I am not sure, and which I have not marked. These were received in less than two months.

* * *

Come Along, You Cotton Planters!

From D. M. Dunbar, Box 641, Cotton Plant, Arkansas

I HAVE a few DX remarks to make. I built a receiver by the directions of Ortheus Gordon in Jan. 20th issue of RADIO WORLD, using Kellogg 43 condenser, De Forrest 50 and 75 H. C. coils, Na-ald socket, Freshman variable grid leak and condenser. When completed this circuit brought in the following places all clear and fine: WOC, WHB, WOAI, KSD, WDAP, WDAJ, WSB, WOS, WDAF, KFAF, WBAP, WLAG, WMC, WCX, WHAS, WSY, WKY, KWH, KFI, WAAP, WLK, WLW, WBL, WHA, WGAY, and last of all I have had WGY five times straight running.

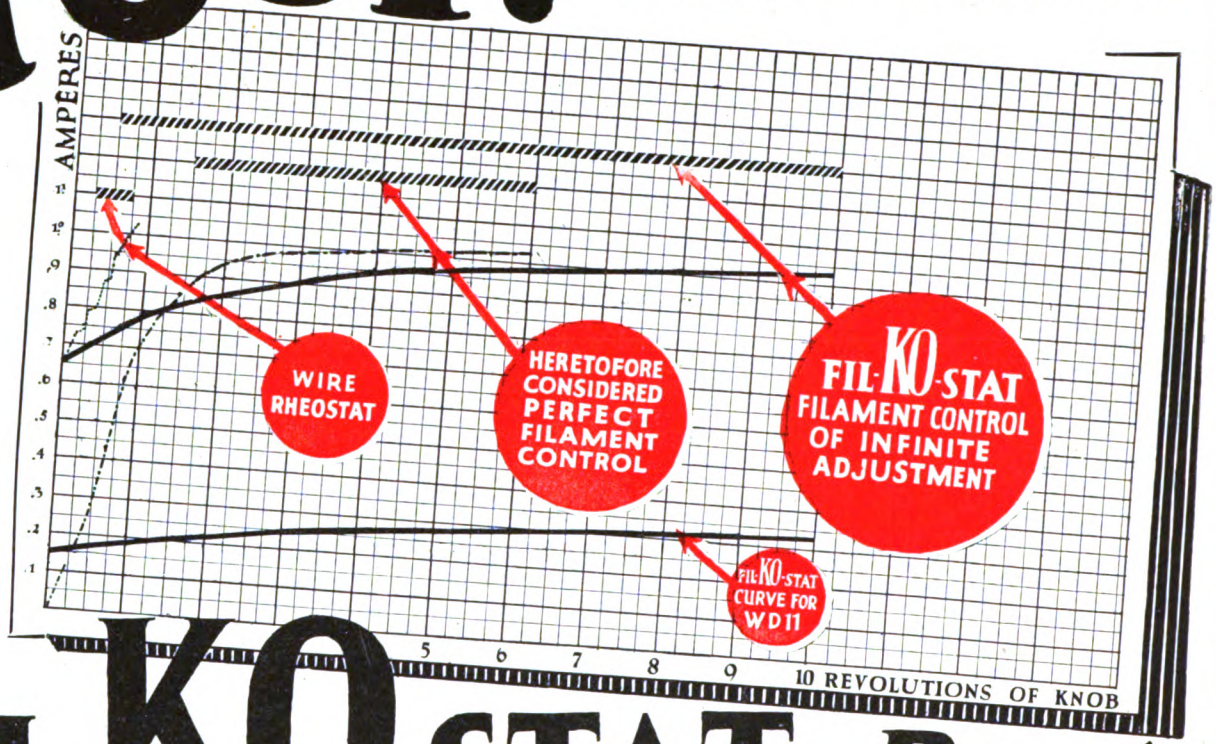
Proof!

Graphic proof of FIL-KO-STAT superiority as shown here can be had in any laboratory equipped with Bureau of Standards Instruments.

Practical proof of FIL-KO-STAT superiority is evident the moment you put FIL-KO-STATS in place of the devices you now use to regulate filament action.

Here's the Comparison of Fine Adjustment Control Range of FIL-KO-STAT with Rheostats and Other Filament Controls Clearly Indicating How FIL-KO-STAT Excels and Showing Wherein it Permits Perfect and Gradual Current Increase With Infinite Adjusments



FIL-KO-STAT *Best* Filament Control

The filament kontrol of infinite adjustment
FIL-KO-STAT
CURRENT INCREASE PERFECT AND GRADUAL
LIKE THE RISING SUN
Trade Mark Registered

Infinitesimal Control
of Electronic Flow

Definite Off
indicating complete "A" Battery disconnection.

Fine Adjustment
starts where tube *begins* to function.

At Full On
Resistance practically zero.

Absolutely Silent
Non-michrophonic, free of all noises.

No Current Variations
Resistance constant at any setting.

No Disks to Break or Chip
Resistance element so finely divided further division impossible.

GUARANTEED

The FIL-KO-STAT is to all purposes "fool proof". Each instrument is packed with the maker's guarantee that it will be replaced if broken within one year.

Manufactured by
DX INSTRUMENT Co
HARRISBURG PA.

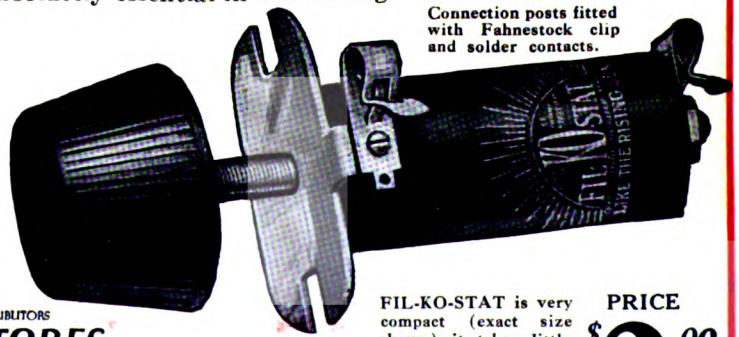
You have been eagerly waiting for just this instrument Mr. Set Builder, amateur or manufacturer. It marks a step forward in Radio. It is not an adaptation of some old method of current control. It is not a rheostat. IT IS A FILAMENT CONTROL, distinctly designed to utilize the great tuning posibilities of the vacuum tube itself.

Its superiority is proven by every test. It regulates the FILAMENT HEAT. It gives absolute control of the ELECTRONIC FLOW and consequently permits THE FINEST TUNING POSSIBLE.

Perfect and gradual increase of filament heat assures longer life to the tube. Fine adjustment of fractional currents makes it ideal for use with Dry Cell tubes.

And infinitesimal control of electronic flow gives a corresponding control of fine detection so absolutely essential in DX tuning.

The time to replace all other filament control devices with FIL-KO-STATS is *now*. Say "FIL-KO-STAT" to your dealer today. If he has none in stock send his name and your remittance direct to



Connection posts fitted with Fahnestock clip and solder contacts.

SOLE INTERNATIONAL DISTRIBUTORS
RADIO STORES CORPORATION

"Of all the innumerable crystal sets, none can even remotely compare with the NATIONAL AIRPHONE"

DR. H. BORDEN CLARKE & CO.
Largest Wholesale Radio Service in Eastern Canada
CLARKE BUILDING
1034-38 Barrington St.

NATIONAL AIRPHONE CORPORATION,
New York City, U. S. A.

Halifax, Canada, February 5, 1923.

Gentlemen:

I wrote you some time ago that we intended testing out your National Airphone Crystal Set for long distance work.

The splendid results allow me the pleasure of informing you that your modest claim of Distance Range is altogether too conservative.

Together with several responsible friends I am willing to testify before any legal agent that we have received complete, concise, clear and natural programs from WGY, New York, Newark, N. J., and Philadelphia Pa.—besides two other unknown stations of long distance.

Our aerial is the average 100 foot one, our office location is very low indeed, near the harbor shore.

Further, slipping your compact little set into my hunting jacket pocket I recently went back in the hills to my camp, hunting; throwing a short wire over a pine tree and in the cabin window. I received that evening two Halifax stations and WGY very clearly. (Halifax, N. S., is about 800 miles northeast of the nearest station mentioned herein.)

Of all the many innumerable Crystal sample sets sent me for testing, none can EVEN REMOTELY COMPARE WITH THE NATIONAL AIRPHONE: WORKMANSHIP, APPEARANCE, POWER, RANGE and COMPACTESS PLACE IT FAR ABOVE ALL.

Yours very sincerely,
(Signed) H. B. CLARKE.

HBC/ED

READ THE TESTS

NATIONAL AIRPHONE CORPORATION,
16 Hudson Street,
New York, N. Y.

Ridley Park, Pa., December 28, 1923.

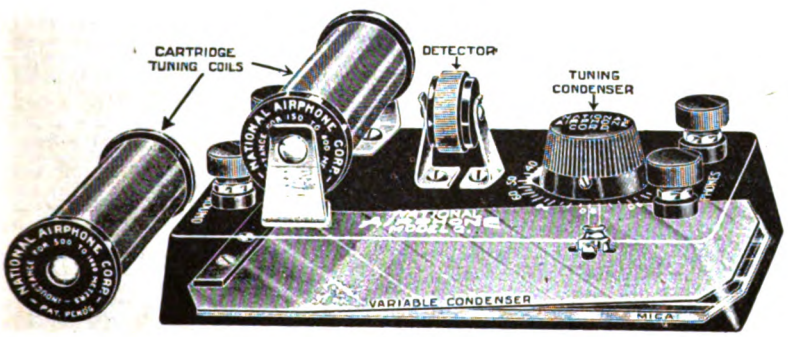
Gentlemen:

Received the two Gold Grain Detectors shipped on the 23rd, and put one in a set using three stages of radio frequency amplification and two audio employing three tubes.

It may interest you to know that I actually got 50% better results as regards distances received with your detector than with a tube and there was no comparison as regards quality of music inasmuch as the parisitic noises generated in the Vacuum Tube when used as a detector were absent. In fact I got less noise of an objectionable character with three stages of audio frequency after your detector than I do with two after a tube detector.

Last night I listened to Havana, Atlanta, Pittsburgh and Davenport without changing the setting of the detector and what is more remarkable is the fact that even with three steps of radio ahead of your detector the powerful currents generated from receiving WFI and WIP (not 10 miles away) were not sufficient to destroy the sensitivity of this remarkable piece of apparatus.

Yours very truly,
(Signed) J. R. BAISLEY.

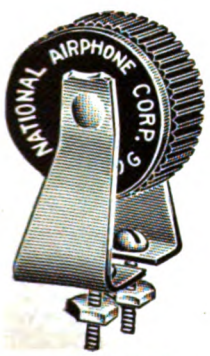


NATIONAL AIRPHONE
MODEL G

The most practical radio set ever made. It is so simple that you need know nothing of radio to operate it. Even a child can get perfect results. No unnecessary complications of any sort. Nothing to fuss with, no batteries, no tubes. No time lost in making adjustments. Just turn the knob and listen. No cost of upkeep or maintenance of any kind.

Complete as shown with 2 Interchangeable Inductance Coils $12.50

Reproduces voice and music in natural color and tone without distortion



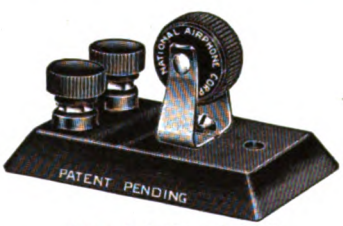
(Actual Size)

"GOLD GRAIN" DETECTOR
For Panel Mounting

$2.00

Can be fitted to any radio receiving set. A revelation to users.

"PUTS THE JOY IN RADIO"



(Size 2 1-16′ x 3 1-4″)

"GOLD GRAIN" DETECTOR

Mounted on base with two binding posts..... $2.50

We are the originators and sole manufacturers of the super-sensitive, semi-automatic "Gold-Grain" Detector, the highest development in Tubeless reception. This Detector consists of an air and moisture proof cartridge, hermetically sealed, in which is enclosed the contact element of pure gold. Has no catwhisker, eliminates hunting for sensitive spots. Simply turn the knurled cylinder and tap lightly with the finger. New contacts are established instantaneously. It gives the clearest and loudest reproduction of all sounds without distortion.

WIRING A HOUSE. By Herbert Pratt. Shows a house already built; tells just how to start about wiring it; where to begin; what wire to use; how to run it according to insurance rules; in fact, just the information you need. Directions apply equally to a shop. Sixth edition. COLUMBIA PRINT, 1493 Broadway, N. Y. C. Price, 25 cents.

STANDARD ELECTRICAL DICTIONARY—By Prof. T. O'Conor Sloane. Just issued an entirely new edition brought up to date and greatly enlarged—as a reference book this work is beyond comparison, as it contains over 700 pages, nearly 500 illustrations, and definitions of about 6,000 distinct words, terms and phrases. The definitions are terse and concise and include every term used in electrical science. 767 pages, 477 illustrations. (See page 18 for fuller description.) Price, $5.00. The Columbia Print, 1493 Broadway, New York City.

EXCHANGE LETTERS with friends everywhere. Pleasant pastime. Information for stamp. Smith, Box 3125, M. Portland, Ore.

VACUUM TUBE RESULTS WITH A CRYSTAL SET!—Cover distance with a "PT" ULTRA-SENSITIVE CONTACT in your crystal detector. Beats gold and other ordinary catwhiskers. DOES NOT JAR OUT. Using the "PT," Myrle Wood heard over 43 broadcasting stations in a thousand mile radius! Other users testify: "Heard new stations on first adjustment. Has all advantages you claim. Receives music so loud it hurts my ears." The "PT" has received 3,300 miles through static. Price only twenty-five cents. "PT" CRYSTAL CONTACT COMPANY, Box 1641, Boston, Mass.

FOR SALE—Paragon Regenerative receiver, R.A.10, Detector, and two-step D.A.2. Both $110.00. Crosley two tube set, $25.00. All apparatus new and guaranteed. Write Philip Coblentz, Middletown, Maryland.

VARIABLE CONDENSERS at factory prices. 3 plate, $1.05; 11 plate, $1.35; 21 plate, $1.60; 43 plate, $2.05. Send cash with order. GREENLEAF, 34 Merchants' Row, Boston, Mass.

BATTERIES—Edison Storage "B" Battery Elements, 5c per pair; 18 will make one 22.5 volt Battery. GILMAN'S BATTERY SHOP, Chelsea Sq., Chelsea, Mass.

EXCHANGE JOLLY, INTERESTING LETTERS through our club. Stamp appreciated. Betty Lee, Inc., 4254 Broadway, New York City

VERNIER VARIABLE CONDENSERS—Capacity, .0006. $1.48 postpaid. Fully guaranteed. Cherpeck Company, 3123 Davlin Court, Chicago.

FOR SALE—Variometers and variocouplers, $3.00 each, 3000 meters. Receiving transformers, $6.00. Anthony Sini, Box 123, Shoreham, Long Island, N. Y.

OLD MONEY WANTED—$2.00 to $500.00 EACH paid for hundreds of Old and Odd Coins. Keep all old money. Send 10 cents for New Illustrated Coin Value Book, 4x6. You may have valuable coins. Get posted. We pay CASH. Clarke Coin Company, Ave. 83, Le Roy, N. Y.

HOW TO BECOME A SUCCESSFUL ELECTRICIAN—By Prof. T. O'Conor Sloane. An interesting book from cover to cover. Telling in simplest language the surest and easiest way to become a successful electrician. The studies to be followed, methods of work, field of operation and the requirements of the successful electrician are pointed out and fully explained. 202 pages. Illustrated. Nineteenth revised edition. Cloth. Price, $1.50. The Columbia Print, 1493 Broadway, New York City.

A COURSE IN MECHANICAL DRAWING—By Louis Rouillion. The author has written a most practical book on the subject of Mechanical Drafting. It fully explains the art of Drawing, Lettering and Dimensioning. It is, by far, the most practical book ever published on this subject, for use in day and evening schools, and more especially adapted for the teacher and for self instruction. Fifteenth edition, revised and enlarged. Fully illustrated. Oblong. COLUMBIA PRINT, 1493 Broadway, N. Y. C. Price, $1.50.

BUILDERS AND EXPERIMENTERS. Do you know that the Reflex circuit is one of the most interesting circuits to construct? You can not guess how much fun you are missing if you fail to try out at least one of these circuits. See RADIO WORLD issues of Feb. 24 and March 3. They contain two fine articles by W. S. Thompson, with plenty of new Reflex circuits to experiment with. Don't miss these! 15c. a copy. RADIO WORLD, 1493 Broadway, New York City.

DO YOU WANT TO SAVE MONEY in making your set? Send for the Jan. 27 issue of RADIO WORLD, containing a full-page drawing of how to make filament control rheostats, as well as an easily understandable text, which makes the construction easy. 15c a copy, or start your subscription with this issue. RADIO WORLD, 1493 Broadway, New York.

SUPER-SIMPLICITY CIRCUIT—1,000 to 1,500 miles on one tube, one control, 150 to 25,000 meters. No rheostat, storage battery, vario coupler, variometer, 3-coil mounting, variable inductance, taps or radio frequency. Nothing to guess about. Complete hook-up and particulars, $1.00. No checks. Build your own. Save 50% and get better results. RADIO EXPERIMENTAL LABORATORY, Box 194A, Berkeley, Calif.

GUARANTEED VARIOCOUPLERS, $2.25.—RADIO ASSEMBLY, 1109 Valley St., Joplin, Mo.

SOLDER YOUR RADIO CONNECTIONS with Radsol, the new soldering paste. Price, 20 cents. Dealers write. DAVIS PROCESS CO., 219 Devoe St., Brooklyn, N. Y.

AGENTS—Are you interested in radio? If so drop us a card. We have a proposition no live agent should turn down. Meets the needs of 90 per cent. of the public. THE WILKENDA CO., 500 Fifth Avenue, New York City. Dept R.W.

CASH FOR OLD GOLD, Platinum, Silver, Diamonds, Liberty Bonds, War, Thrift, Unused Postage Stamps, False Teeth, Magneto Points, Jobs, Any Valuables. Mail in today. Cash sent, return mail. Goods returned in ten days if you're not satisfied. OHIO SMELTING CO., 337 Hippodrome Bldg., Cleveland, Ohio.

HOW TO REPAIR Vacuum Tubes. Complete literature, $1.00. Box 103, Station C, Toledo, Ohio.

RAND-McNALLY RADIO MAP OF UNITED STATES—Is 28 x 30 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover. Price, 35c. The Columbia Print, 1493 Broadway, New York City.

MODEL MAKING—By Raymond Francis Yates. A new book for the mechanic and model maker. This is the first book of its kind to be published in this country, and all those interested in model engineering should have a copy. The first eight chapters are devoted to such subjects as Silver Soldering, Heat Treatment of Steel, Lathe Work, Pattern Making, Grinding, etc. The remaining twenty-four chapters describe the construction of various models such as rapid fire naval guns, speed boats, model steam engines, turbines, etc. 400 pages. 301 illustrations. Price, $3.00. The Columbia Print, 1493 Broadway, New York City.

TWENTIETH CENTURY BOOK OF RECIPES, FORMULAS AND PROCESSES—Edited by Gardner D. Hiscox. This book of 800 pages is the most complete book of recipes ever published, giving thousands of recipes for the manufacture of valuable articles for every-day use. Hints, helps, practical ideas and secret processes are revealed within its pages. It covers every branch of the useful arts and tells thousands of ways of making money and is just the book everyone should have at his command. The pages are filled with matters of intense interest and immeasurable practical value to the photographer, the perfumer, the painter, the manufacturer of glues, pastes, cements and mucilages, the physician, the druggist, the electrician, the dentist, the engineer, the foundryman, the machinist, the potter, the tanner, the confectioner, the chiropodist, the manufacturer of chemical novelties and toilet preparations, the dyer, the electroplater, the enameler, the engraver, the glass worker, the gold-beater, the watchmaker, the jeweler, the ink manufacturer, the optician, the farmer, the dairyman, the paper maker, the metal worker, the soap maker and the technologist in general. A book to which you may turn with confidence that you will find what you are looking for. A mine of information up-to-date in every respect. Contains an immense number of formulas that everyone ought to have that are not found in any other work. New edition. 807 octavo pages. Cloth binding. Price, $4.00. The Columbia Print, 1493 Broadway, New York City.

Address Wanted:—The address of Arthur Kimberling. Write Business Dept., Radio World, 1493 Broadway, New York City.

Moving Pictures by Radio Predicted by Jenkins

THE American family will be able, in the near future, to gather about the radio set in the parlor and see a complete moving picture show. This is the confident prediction of C. Francis Jenkins, inventor, who is putting the finishing touches at his laboratory in Washington, D. C., on apparatus for transmitting and receiving moving pictures.

Mr. Jenkins recently startled the radio-fascinated public by the transmission of photographs of Harding, Coolidge and other notables from Washington to Philadelphia, the first long-distance transmission of photographs by radio ever accomplished. This device was illustrated and described in RADIO WORLD for March 17, 1923.

"I will have my apparatus ready for a trial within a very short while," Mr. Jenkins is quoted as saying. "I have nearly finished it, and am absolutely confident that the experiment will be successful. There is nothing in the way of transmission of moving pictures but a matter of speed, and I am sure I can provide for that."

Hammond Sells 200 Radio Patents

RADIO devices developed by John Hays Hammond, Jr., primarily for war-time use by the government, which include methods of operating aerial and marine torpedoes and maneuvring battleships without personnel for target practice, have been sold, it was announced in Washington, D. C., last week, to the Radio Corporation of America and the American Telephone & Telegraph Company.

The government, however, will retain an option on all of the devices for military use and for experimentation with aircraft bombing. Mr. Hammond and his assistants will be retained as consulting engineers by the Radio Corporation. Approximately 200 separate patents have been conveyed to the commercial companies in the transaction.

Parts to Make Up

FLEWELLING CIRCUIT

No ground, no aerial. Portable; can be carried in your car, train or camp. Will get long distance on a loop.

Simple to operate; can be worked with W. D. 11 Tube.

1 Spec. Bakel. Variocoupler	$2.90

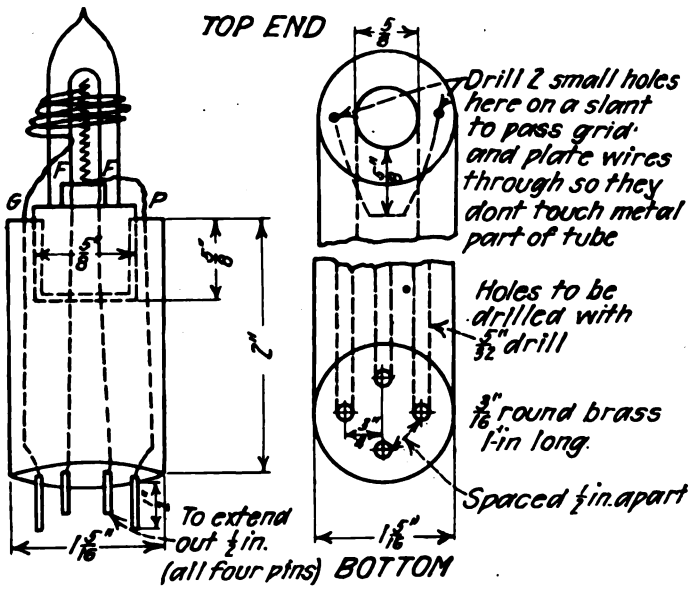
Making a Socket Adapter for a Peanut Tube

By P. F. Metzler



TOP END
F
F
G
P
5/8
1 1/16"
To extend out 1/4 in. (all four pins)
BOTTOM
5/8
Drill 2 small holes here on a slant to pass grid and plate wires through so they dont touch metal part of tube
Holes to be drilled with 5/32" drill
3/16" round brass 1-in long.
Spaced 1/4 in. apart
1 1/16"

SOCKET adapters for W. T. 501 peanut tubes are scarce and hard to get, so it's up to the amateurs to make them for themselves. The one herewith described will be found to be very satisfactory, as it can be shifted from one socket to another without disconnecting any wires or running the risk of breaking the lead from the grid or plate.

The sketches show all details of making this adapter. No. 1 gives a general outline as it appears when finished. No. 2 shows the top view, and No. 3 shows the bottom view where the four brass pins are placed. The pins are made out of 3-16 round brass, one inch long, slightly rounded.

You will also have to get a round wood piece two inches long and 1 5-16 inches in diameter. In this drill a hole on one end ⅝ in diameter and ⅝ deep. On the other end drill four holes with a 5-32 drill all the way through into the ⅝ hole. Then on top on each side of the ⅝ hole drill two more small holes so that they will come out at bottom of ⅝ hole. These are for the grid and plate series. Next, solder onto the tube four fine wires leading from the grid, plate and filament contacts. These go through the four 5-32 holes.

Next, drive in the brass pins ½ inch. Solder the four wires to these as close to the base as possible. Have a socket handy and make the pins correspond with the grid, plate and filament. Be very careful about this, as you may burn out a tube if you place it in the socket incorrectly.

Next, drive a small pin in the side to hold it in the socket. You might place the adapters in the socket in the right place and press down slightly. Mark with a pencil where the pin belongs. A real small nail cut off about ⅜ inch long will answer, using the point end.

WALCON
Radio Frequency Transformers

Brings in distant stations on a loop—perfect reproduction. No distortion. Awarded Certificate of Excellence by N. Y. Eve. Mail.

THE BEST YOU CAN BUY

WALCON Transformers are tested and guaranteed. Particularly adapted for use with W.D.-11 tubes.

Broadcasting Stations Can Not Send Personal News

BROADCASTING stations receive requests almost daily to send out messages of a personal character. One man requested WGY to send a description of his Airedale pup which was lost and greatly missed by his children. Another asked that the waiting world be informed that his family was well.

Those who make requests for the broadcasting of purely personal matters are informed that the stations are not permitted, under their licenses issued by the United States Department of Commerce, to put anything into the air that might be interpreted as a personal or commercial communication.

Wireless Installations Barred in China

NEWS, said to be from an official source, was sent out from Washington, D. C., last week announcing that the government of China has refused the application of the Westinghouse Electric International Corporation for permission to import radio materials into China and to establish broadcasting and receiving stations.

Permission was refused by the Chinese Minister of War, it was asserted, on the ground that radio apparatus is contraband of war and therefore cannot be brought into China, upon pain of seizure. Reference was made by the Chinese authorities to the resolutions concerning the radio adopted by the Washington Arms Conference, one of which declares that all stations operated within the territory of China by foreign governments or the citizens or subjects thereof under treaties or concessions shall limit the messages sent and received by the terms of the treaties or concessions under which they are established. The American contention is that none of the arms conference treaties are yet in effect, not having been ratified by all the signatories.

Attention also was called to the resolution providing that stations maintained without the authority of the Chinese Government shall be transferred to the Chinese and operated under direction of the Communications department.

The refusal of the Chinese Government is regarded by American interests in China as a further example of the growing tendency of Chinese officials to quibble over every technicality when foreigners are involved, and to read extraneous privileges and precepts into international agreements.

Vesper Services at WGY Are Multiplied

EVERY Sunday afternoon a little group of people assemble in the radio studio of WGY, in the midst of the towering factory buildings of the General Electric Company at Schenectady, N. Y., and conduct a vesper service, including organ selections, hymns, Scripture reading and sermon. The group in the studio is small, but many thousands in city and country participate in the devotions.

These services not only enter many homes, but they are multiplied by means of receiving sets and loud-speakers, and made to furnish the religious inspiration of other gatherings in distant places. For example, the Railroad Y. M. C. A. at Oneonta, N. Y., no longer arranges for a special afternoon service, but instead receives WGY; and, according to a letter from the general secretary, A. C. Lange, "these services come through very clear, and are enjoyed by all who attend."

Charles J. Clark, a merchant at Holland Patent, N. Y., informed WGY that the Baptist Church at that place was closed recently on account of the scarcity of coal. He invited the congregation to meet with him in his home, and they listened to the service broadcast by WGY.

Radio Killing Phonograph Sales

C. J. ROSENTHAL appeared before the the Second National Radio Conference, at Washington, D. C., last week, claiming that, unless they paid royalties to the writers of songs and music used in their programs, the owners of broadcasting stations would be prosecuted under the copyright law. He was talking in defense of the Society of Authors, Composers and Publishers of America, and said in part: "The situation is serious. Radio is affecting the sales of sheet music and phonograph records. The radio sets are placed on top of the phonograph, which are not used any more. In New York, St. Louis, and Newark, N. J., apartments are being built with attachments to permit the use of radio in every apartment, and I believe that this will eventually be done all over the country.

When queried as to whether the song writers and phonograph people do not derive benefit from the advertisement that they gain through the broadcasting of the songs and music he replied that the benefits were negligible.

New Scientific Term

TWO young chaps with the usual boyish interest in scientific achievements were discussing an enunciating device used in a certain London store.

"It yells out the day's bargains," one explained. "They call it a stentorphone.'"

"Aw, we have one of those at our house," replied the other boy, with a twinkle. "We call ours 'Ma'!"

Young Hopeful Learns the Code

Little Johnnie was just learning the radio code, and, after the habit of the animal, was practicing most of the time somewhat as follows: "Dit-dit-dit, dit-dah, dah-dit-dah-dah." This finally got on his mother's nerves, and she asked him to stop, saying: "Johnnie, if you don't stop dittling I am going to dah-day you, and then tell your father, who'll dah-dee you so that you will be all dahed out of dum-dum."

National Radio and Electrical Exposition, San Francisco

THE National Radio and Electrical Exposition, which will be held in the Civic Auditorium, San Francisco, April 3 to 8, 1923, has been endorsed by the local electrical organizations by unanimous vote. They have agreed to co-operate in making the show a success.

The personnel of the San Francisco advisory committee, headed by J. C. Johnson, includes Louis F. Leurey, president of the San Francisco Electrical Development League; J. Mahoney, secretary and treasurer of the San Francisco Electrical Development League; H. C. Hopkins, president of the Pacific Radio Trade Association; R. E. Fisher, vice-president of the Pacific Gas and Electric Company; Earl Brown, president, California State Association of Electrical Contractors and Dealers; O. H. Miller, vice-president, Pacific Radio Trade Association; Victor Lemoge, president, San Francisco Association of Electrical Contractors and Dealers; Arthur Rowe, Garnett Young Company; Max Lowenthal, secretary and treasurer, Pacific Radio Trade Association; .R. D. Oyler, treasurer, California State Association of Contractors and Dealers; A. H. Halloran, editor and publisher, *Radio Magazine;* E. Martin, vice-president, San Francisco Association of Electrical Contractors and Dealers; J. W. Redpath, secretary, California State Association of Electrical Contractors and Dealers; Clyde Chamblin, president, California Electrical Construction Company, and A. Elkens, secretary, San Francisco Association of Electrical Contractors and Dealers.

Already reservations for approximately 75 per cent. of the total number of booths have been received by Mr. Johnson, who further advises that plans for the exposition will be completed in a few days, when work on the decoration of the Auditorium and the construction of booths will be started.

Dr. DeForest's "Phonofilm" Demonstrated

THE "phonofilm," a device which reproduces sounds synchronized with motion pictures, was demonstrated last week by its inventor, Dr. Lee De Forest. Dr. De Forest uses a standard motion picture camera and projection machine with his sound recording and reproducing attachment. In recording sounds a transmitter is used which transforms the sounds into electric waves. These waves are amplified and modulate an oscillator, connected with which is a gas-filled tube, called the photion. The intensity of the light in this tube varies according to the modulations of the oscillator, and its variations are recorded photographically on the margin of the film. In reproducing the sounds the process is reversed. Dr. De Forest will shortly demonstrate the phonofilm before the New York Electrical Society, and after that in a New York motion picture theater.

French Experts on Track of Wildcat Radio Station

FRENCH radio experts are convinced that it is a British or an American station which sends out only 400-meter wave lengths and sometimes jams the programs from the Eiffel Tower. These experts are convinced that it is not a German station, as at first suspected, since the voice of the sender is heard frequently breaking in with remarks in English. The sender violates radio rules by not giving a symbol, but military observers are adapting an apparatus to measure wave lengths and the direction from which they come, with the intention of complaining officially of the existence of the "zero" post.

CROSLEY MODEL X

This Crosley Model X, costing only $55—is probably the most complete and satisfactory receiving set on the market today. Owners of the Crosley Model X have tuned in practically every broadcasting station in the United States, hearing the selections clearly and distinctly.

The feature of the Model X success is the one stage of Crosley Tuned Radio Frequency Amplification before the detector. By means of this, the incoming sounds, even from remote stations, are amplified many times before they reach the detector.

Other popular Crosley Models are No. VI, a two tube set at $28 and No. VIII, a three tube set at $48.

"Old King Tut"

USED TO LISTEN TO REASON

That's why we made

Vac-Shields Non-Magnetic

Iron and steel have little use in Radio work, because they cause Hysteresis—High Frequency currents having a great affinity for these metals are quickly absorbed, resulting in decreased signal strength. Then again Magnetized metals when brought close to a Vacuum Tube cause an excessive flow of Electrons from the filament, which shorten the life of the Tube.

SIX REASONS WHY You Should Equip Your Set With "NON-MAGNETIC" VAC-SHIELDS

1—They are Non-Magnetic.
2—You do not need to Burn your Filament so Bright.
3—Prevent Interstage Electro Static Coupling.
4—Stop Howling and Distortion.
5—Enable you to Tune in Distant Stations.
6—Guard Tubes Against Breakage.

Order today by mail, Postpaid, $1.00.

The First 50 Years

"The first fifty years are the hardest."

In publishing, the first year is generally the hardest. Starting a new publication without a reader or an advertiser is a REAL undertaking—and what makes success? We believe it is giving the most valuable information in the most interesting form.

RADIO WORLD'S first subscribers mostly took it for three months at $1.50. At the end of 90 days came our first test—would they renew? To our agreeable astonishment 90 per cent. of them renewed but not for three months but sent their little six dollars for a year's subscription.

Our weekly increase in circulation is now averaging from fifteen hundred to two thousand, and if we can only hold out at this rate for fifty years RADIO WORLD will have the largest circulation of any weekly in the world. Even today at the end of our first year RADIO WORLD is the most profitable medium to our advertisers, and gives as good, often better, returns than the older monthly radio publications, which charge two or three times our advertising rates.

Readers, we thank you, and by the same token we ask you to suggest how we can make RADIO WORLD more interesting to you. Write and tell us your radio problems—what you want to know most, tell us of the articles you like, and especially tell us of the ones you don't like or disagree with—and so make RADIO WORLD for the coming year truly YOUR Radio Weekly.

It will continue to be our endeavor to give you ALL the news in radio from one to six weeks in advance of any of the radio monthlies.

Commercial Broadcasting in Germany

AFTER four months of experimenting the Express Service Company (Eildienst Gesellschaft), Berlin, has begun a daily service of financial and commercial news broadcasting to subscribers in various parts of Germany, according to a report to the Department of Commerce from Consul E. V. Richardson, Berlin. This company is financed by German capital, and is purely a private undertaking. Having arranged with the national government for the use of the radio station at Koenigswusterhausen on a limited basis for a definite period, a regular service of financial news is received from the United States, Switzerland, Sweden, and other countries, via the high-power station at Nauen, Germany.

This information is broadcast immediately by radio telephone to subscribers of the company. These number at present about 800, and are mostly banks and industrial institutions located in some 200 towns and cities. It is expected that New York quotations handled by this service will be available generally to subscribers within ten minutes of their dispatch from New York.

Each subscriber rents from the company the necessary receiving apparatus, paying for the service itself an annual fee of 300,000 marks, and for the apparatus an annual rental of approximately 200,000 marks. There are 2½-hour schedules daily, beginning at 9:30 a. m. and 5 p. m. The Express Service Company is represented in New York by a large American news agency.

Cuba and California Answer "Roll Call" in Chicago

CHIMES in Havana played "Home, Sweet Home," and a violinist in San Francisco gave a solo on a recent night for an audience in Chicago in a demonstration of overhead, underground and submarine telephone cables, and the wireless telephone.

Twenty cities from the Pacific Coast to Cuba answered when General John J. Carty, vice-president of the American Telephone and Telegraph Company, conducted a "roll call" during an address on world communications. As each station answered a light flashed upon a giant map, and the far-away operator, his voice magnified by amplifying devices, spoke to the Commercial Club. Among cities answering the roll call were Richmond, Va.; Philadelphia and Pittsburgh.

Radio Does Change 'Em

CHARLES M. SCHWAB recently delivered an address in New York which was heard by his mother in Loretta, Pa., via radio. And afterward, it is said, she wrote: "Charlie, you don't seem to be the same boy you were fifty years ago."

Yours Sincerely **Greenwich Radio Co.**

Second Edition of "Radio Constructor"

THE second edition of the "Radio Constructor" is a valuable book for all radio enthusiasts to have handy. Not only is it right up to the minute with the most recent developments in hook-ups, but it also embodies special features to be found nowhere else. Full details are given about the following types: Regenerative set with two-step amplifier for the W-D 11 tube; short-wave regenerative tuner and amplifier in separate units; radio frequency two-stage amplifier; honeycomb receiver and amplifier; long-distance receiver; reflex amplifier; Reinartz tuner, and the Flewelling circuit.

In addition to the plans and description, the maker of the set is supplied with a complete panel layout containing full dimensions. This makes it extremely simple for the builder of the set to lay out his panel without waste of time and patience.

Another excellent feature is a complete list of all the broadcasting and mercantile stations throughout the United States and Canada, listed in alphabetical order. This enables the listener to tell at a glance exactly what he is capable of receiving with his particular set. With its valuable text, diagrams, and information, no fan should be without this book.

Explanation to Advertisers

A considerable number of advertisements for this Anniversary Number of RADIO WORLD were received too late for publication.

The extra large edition required to meet advance orders necessitated going to press promptly. Therefore, it was incumbent upon the publishers to omit advertisements not received according to schedule.

These omissions are regretted, and it is hoped that advertisers in the future will adhere to publication time schedules, which are becoming more exacting as the circulation of RADIO WORLD is steadily increasing.

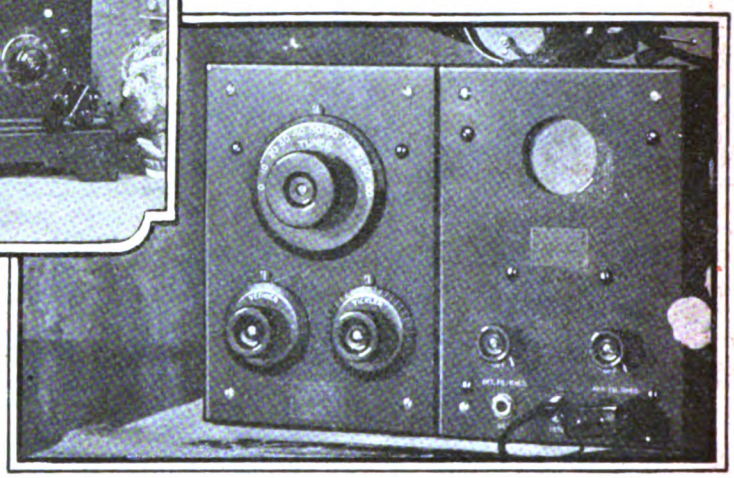
Radiola RC

Radiola RC is one of the nation's most popular long distance receivers. Compact—efficient—with a sensitive detector, and two stages of amplification, for louder, clearer reception of distance. Finely made—and attractively finished—of solid mahogany.



Radiola V

Radiola V is built for a life time—solidly—ruggedly. In principle and performance, it is the same as Radiola RC—detector with two stages of audio amplification. With the same long distance reach. And the same keen sensitiveness. A pleasing and unobtrusive piece of furniture in its neatly finished casing. Dependable always—and simple enough for any one to operate.

A New Improvement Lowers the Cost!

Dry Cells Replace Storage Batteries

A new vacuum tube has made it possible. Radiola V and Radiola RC have been topping them all in popularity for dependability and long range—receiving over thrilling distances—up to 1,500 miles and more. Now both are converted to dry battery operation. This means greatly lowered cost—does away with bulky storage batteries—gives the far-away farmer the same good service it gives the city man.

No more need for expensive storage battery and charger. A big saving! And a saving made greater by the new offer—a combination offer of receiver and accessories—complete at a price remarkably low.

ILLUSTRATED WEEKLY

"WIRED WIRELESS" ON NEW YORK TROLLEY CAR

(C. Wide World Photos)

The Third Avenue Railway Company, New York City, in conjunction with the General Electric Company, has completed a series of experiments where radio carrier currents are used on the feed and trolley wires of its overhead system as a means of communication between widely separated points of its entire system. The transmitters and receivers are similar in many respects to the general run of broadcasting apparatus.

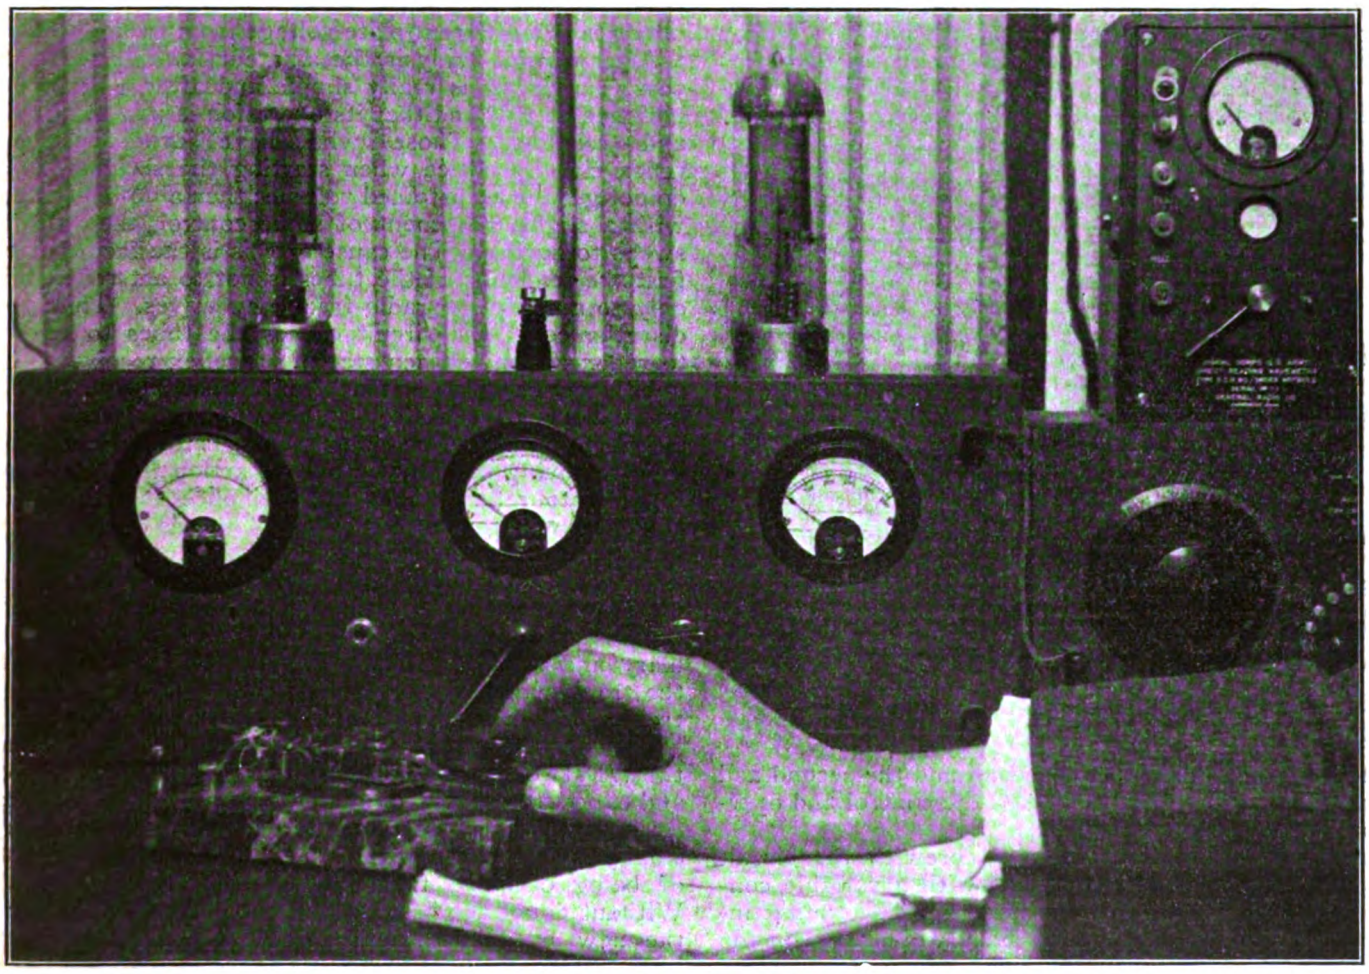
Amateur Builds 2,500 Mile Transmitter

By John Kent

MUCH attention in the past has been paid to receiving sets and very little to transmitters, although they are just as interesting and, to a great many experimenters, are far more intriguing.

The transmitter illustrated herewith was built by Paul Haus, a New York amateur whose call is 2VK. The set incorporates several novel features which would benefit prospective builders of transmitters. The set proper is rated at 150 watts and has a reliable working range of 1,500 miles, but reports have been received that show he has been heard 2,500 miles away.

As shown in the illustration, the antenna is connected directly over the center meter of the set and serves as the antenna for both the receiver and transmitter, change-over being made by means of the switch directly under the meter. This switch is a converted Amrad throw switch and it is possible to throw directly from transmitting to receiving with a flip of the hand. The receiver is shown connected to the right hand binding posts of the set. On either side of the switch are shown two jacks by means of which either chopper or key can be used for either ICW or straight CW.



(C. Photonews, N. Y.)

Extremely neat and compact 150 watt transmitter constructed by Mr. Paul Haus of New York City, which has covered 2,500 miles. It can transmit either interrupted CW or straight CW.

The three meters are the voltmeter, thermo-ammeter and milliameter, by means of which accurate check can be kept on the working of the set. It uses two 50 watt tubes which are located on top of the cabinet. The Heising system is used, changed to accommodate the builder's needs for CW instead of voice.

A point of note is the direct reading wavemeter located directly next to the transmitter and on top of the receiver. By means of the wavemeter, you don't need to "guess your wave is O. K." but your conscience will never bother you because all you have to do is switch it on and tell.

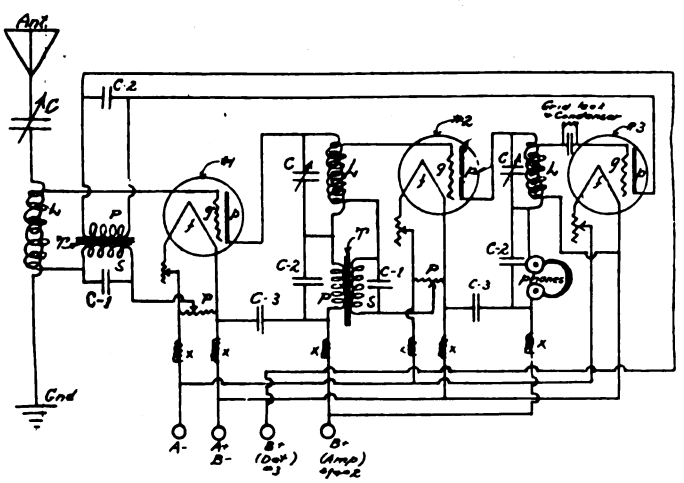
A Novel Three Tube Reflex Receiver

By C. White, Consulting Engineer

RADIO WORLD for Feb. 17, 1923, contains a single tube reflex circuit of my design. The circuit used one tube of combined radio- and audio-frequency amplification and a crystal detector. Many of my amateur friends after giving the circuit a good trial wrote me asking for the extension of the theory to more than one tube. At first there were many obstacles in accomplishing the desired design, but after a little experimenting I have been able to design the circuit that so many fans have been urgently requesting. Although from the diagram the average fan may think that the solution is rather long and complicated, still, the circuit is the most simple, reliable, and economical reflex for amateur use. If the circuit were simplified any more it would cease to be reliable although the price would be lowered. The number of controls have been reduced to a minimum and by the employment of the choke coils (x in the diagram) serious feed-back and oscillation trouble has been effectively avoided. The use of coupling between the tuned



. Circuit described by Mr. White in the accompanying text. This circuit, by the use of the double wound coil L, eliminates one of the controls heretofore supposed to be necessary.

plate circuit of the first and second and the second and third tubes has greatly facilitated the control and operation of the receiver.

As illustrated in the diagram herewith the circuit consists of a main tuning circuit with a variable condenser C and a tuning inductance L. The tuning inductance L is made up of two coils wound one on top of the other, on a 3½ or four-inch tube. The primary coil is wound on the tube with No. 22 D.C.C. magnet wire and has 50 turns. The secondary is wound on top with the same size wire having 40 turns. By the use of these coils the advantages of a coupled circuit are partially realized and the trouble of coupling adjustment and the cost of varicouplers are avoided. Then again, it has also been found from experiment that this receiver functions satisfactorily with the fixed coupling. All the coils marked L are constructed in an identical manner and all the condensers C are 23 plate variables. The condenser C-1 is a .00025 mfd. mica condenser and is used to by-pass the radio-frequency waves across the high impedance secondary of the audi-frequency transformer T. The letter P on the transformer labeled T stands for primary and S for secondary. A potentiometer is placed across the "A" battery in order to be able to afford an ample adjustment of negative potential for the grid circuits of the amplifying tubes No. 1 and No. 2. The potentiometers P should have a resistance of 250 or 300 ohms apiece. The choke coils X should have an inductance of .1 henry and the audio and radio by-pass condenser C-3 has a capacity of .25 mfd. The condensers C-2 are radio-frequency by-pass condensers with a capacity of .001 mfd. A grid leak and grid leak condenser is provided for the grid of the detector tube instead of a potentiometer as used on the grid of the amplifying tubes. Two separate "B" plus terminals are illustrated, one for the detector plate potential supply and the other for the amplifiers plate potential supply. This is feasible because the detector operates at a different plate voltage from the amplifiers.

After careful analysis the amateur fan will discover that this circuit is really simple and after a little experience he will find that its operation is just as simple and reliable. Those who have ever operated reflex circuits notice when starting the set that they do not get the accustomed volume; then all of a sudden, with a slight movement of some control, the volume swells to normal. The cause of this is the fact that at first the tendency of the tubes is not to act reflex but only to amplify the radio-frequency waves. Then the disturbance of the circuit causes the tubes to revert to reflex action. When starting a reflex receiver it is good practice to give it a "crank" just as you would crank your automobile. This cranking is performed by short-circuiting the phone terminals for a second and then removing the short. By this action the tubes are forced into reflex amplifying and once the circuit is started it will not fall out of "step" unless one or more of the tubes start in oscillation, which is next to impossible with a carefully constructed receiver using the illustrated circuit. In assemblying and trying out care should be exercised to test out the transformer primary and secondary connections. By connecting up the transformer as the manufacturer recommends the trouble of getting the coils in backward will be avoided.

Now for a word as to tubes. Do not attempt to use the WD-11 or like type of designed tube in this receiver and expect to get anything more than mediocre results. Such types of tubes have their elements spaced very closely and the radio-frequency amplification capable of being obtained from them is exceedingly small. Without doubt the best tubes to use in this circuit are the new UV201-A Radiotrons or C-301-A Cunninghams. Owing to the large size elements and high vacuum and other desirable characteristics these models are without peers for a reflex receiver. Then again, their low current consumption makes it possible to operate the three tubes with about 25 to 35% less current than one of the older models of the same type. Although these tubes are rated to take five volts at .25 ampere, I have found that they operate very satisfactorily with only four volts on the filament and a much lower current. The high vacuum makes the tube quite noiseless as a detector and highly desirable for this reason in a reflex circuit. Those who have already built this circuit or a similar one say that they would not trade it for any other, no matter what the cost. For distant work it can not be beat.

Behind the Scenes During Radio Broadcasting

By A. G. Popcke

Studio Director, Station KDKA.

CURIOSITY is universal, and no doubt you have wondered what actually takes place in the studio during a radio program. It is very simple and not exciting, yet the performances are given under the closest supervision and governed by principles which have been discovered only by the most thorough research.

The studio is a room about 20 ft. by 30 ft. and 15 ft. high. The walls and ceiling are completely covered with heavy draperies and on the floor is a heavy rug, making the studio free from echo and reverberation, a necessary requirement for the transmission of a pure tone by the microphone.

The furniture is simple; a piano, cabinets containing amplifying apparatus, the necessary switches, chairs, music stands, and such musical instruments as are required. The microphone is supported on an adjustable and movable stand so that it can be moved readily to suit the nature of the performance.

A number of signal lights indicating when silence must be maintained are in plain sight so as to warn all in the radio studio to keep quiet when a performance is being announced and transmitted.

Adjoining the studio is an anteroom for the convenience of the artists, furnished with writing desk, registration book, comfortable chairs, and also a receiving set to pick up the performance being broadcast.

The artists are scheduled to arrive about fifteen minutes before the program is to start, in order that they may become accustomed to the surroundings and to enable the announcer to check the program so it will be sent out without delay during the time scheduled.

The performers are instructed regarding the proper position with reference to the microphone, as the relative positions of soloist, accompanist, and microphone are of fundamental importance in getting good results.

Sound varies inversely as the square of the distance from the point at which it is produced; that is, at double the distance the sound is one-quarter as intense. Voices vary as to resonance, quality and volume. The characteristics of the various musical instruments differ in intensity. These facts make it necessary to exercise great care in properly placing musicians to produce results in your receiver comparable to those heard from the concert stage.

By continually studying the distances at which various classes of performers produce the best results, by noting the nature of the various instruments and voices as to volume and resonance and by comparing the nature of the compositions and their accompaniment we have collected valuable data which enable us to place correctly various classes of performances for best results in transmission. Minor adjustments are frequently necessary after the first selection has been given, particularly to get the proper balance between the voice or instrument and its accompaniment.

Improper placing greatly reduces the effectiveness of good artists, and skill in placing appreciably improves the results with mediocre artists provided they are not off pitch. To the listener, the human element is entirely lacking and a performer's personality cannot compensate in any way for artistic shortcomings. The radio listener is impressed only by the music as he receives it.

The modulation meter is of great assistance to the studio director. This instrument indicates on a scale the intensity of sound transmitted. Sounds which give a reading of over 100 will not transmit without distortion, and, therefore, all music and speech must register below this point. If the meter reads too high, adjustments must be made either by increasing the distance between the performer and the microphone or by reducing the amount of amplification used. The speaking voice registers between 40 and 70; a soprano solo averages about 35 with peaks of 75 and 100 on higher pitches and louder notes. The accompaniment is about 15 to 25. During orchestral selections the meter usually reads between 20 and 80, averaging about 40.

Every program given is carefully checked on receiving sets by several persons, and a detailed report calling attention to any faults or imperfections is made.

The element of stage fright is usually present among new-comers although apparently they are singing only in a small room with practically no visible audience. Everybody realizes that members of the vast audience concentrate their entire attention upon their hearing and a slight slip will not pass undetected.

Interior view of the new KDKA studio at East Pittsburgh, Pa. Dr. Phillips Thomas is listening to a test of his new "glow" transmitter.

In the absence of applause there is nothing to give the performer any moral support, but if a hit is made, telephone calls and telegrams give this support in a very short time.

You have all noted a gradual improvement in the quality of transmission. This has been accomplished by continual research and experimental work by our large force of engineers, improving the various elements that constitute successful radio transmission.

To keep pace with the improvement in transmission strong efforts are being made by our radio broadcasting staff to make our programs of ever increasing interest to our vast audience. To hold the attention of so great a number, the programs must be: Entertaining and interesting, dignified and of high quality, educational to the average listener.

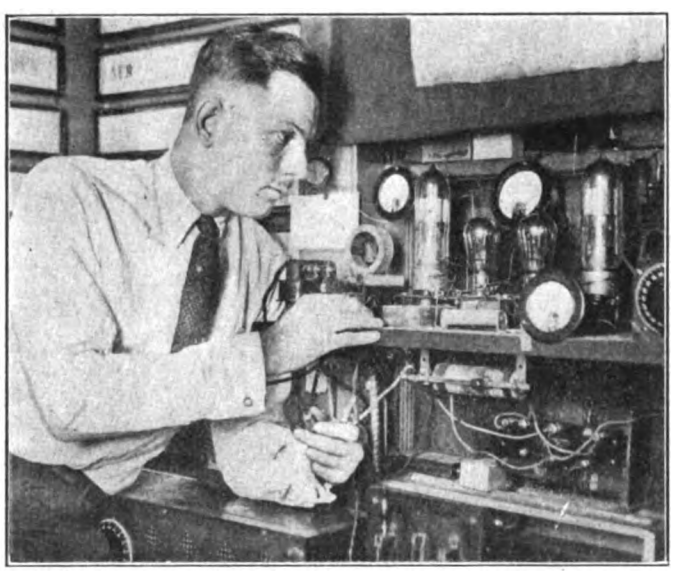
Proceedings of the Second National Radio Conference

Recommendations Mark New Era for Radio Public

THE second National Radio Conference announced on its adjournment, March 24, that its recommendations to the Secretary of Commerce mark a new era for the radio public. It recommended that the interference experienced by broadcasters and listeners be relieved by the opening up of a new wide band of waves by the government and a new assignment of individual wave lengths to broadcasting stations. This is made possible by the opening up of what was previously government reserved waves and the shifting of certain ship waves out of the broadcasting wave bands. The Department of Commerce, acting under its present authority, will be able to establish and enforce the new regulations, and thus bring order in the radio world. Summarized, the important recommendations of the conference were:



(C. Kadel and Herbert)
The Hoover cup, which is awarded annually to the owner of America's best amateur station under the ARRL was awarded this year to Station 2BM, owned by Frederick B. Ostman, 189 Broad Street, Ridgewood, N. J. The illustration shows Mr. Ostman and his transmitter which took the prize.

Previously all broadcasting was concentrated on three wave lengths—360, 400, and 485 meters. Now a new field extending from 222 meters to 545 meters can be created for the purpose. Within that field stations can be assigned individual wave lengths and divided into two classes. The higher power Class "A" stations corresponding to the present Class "B" stations can use the wave lengths between 288 meters and 545 meters, while lower powered stations (new class "B" stations) can use the waves from 222 to 286.

This will enable the higher power stations distributed in 50 localities and comprehensively covering the United States, to be within the reach of every listener. Suitable wave lengths are provided in the recommendations for the more than 500 existing lower power stations.

The report urges that the field of amateur activity be extended by allotting a band extending from 150 meters to 222 meters in place of the waves up to 200 meters now used. The band from 200 to 222 meters can be reserved for high grade continuous wave telegraph transmitting stations operating under special license. Technical and training school licenses can also occupy this band. The report confines spark amateur radio telegraph stations to the band 175 meters to 200 meters.

It also includes the provision that ships using 450 meter waves keep silent between 7 and 11 p. m. and, as soon as possible, readjust their equipment for transmission on wave lengths above 600 meters.

Provision is made in the recommendations for a new field of ship telephone service, enabling persons on shore to talk to those aboard ship. This can be carried out on waves far above broadcasting waves, so that no interference can result.

The reading of telegrams or letters by broadcasting stations should be permitted, says the report, so long as the signer is not addressed in person and so long as the text matter is of general interest.

Another recommendation is that simultaneous rebroadcasting be permitted as a service only on a broadcasting wave length, and with the authorization of the original broadcaster and of the Department of Commerce.

The new regulations recommended are based on a plan submitted by the radio inspectors of the Department of Commerce, and include elements from other plans submitted by the Radio Section of the Associated Manufacturers of Electrical Supplies, The National Radio Chamber of Commerce, the Institute of Radio Engineers, the American newspaper broadcasting stations and several other groups.

It was the unanimous opinion of the conference that the Secretary of Commerce in licensing stations has the authority under the present law to regulate hours and wave lengths of operation of stations, and to revoke or withhold licenses of stations when such action is necessary to prevent interference detrimental to the public good.

The committee also urged that the fullest co-operation be given by those who operate broadcasting stations and by the public with the Department of Commerce in the co-operative adjustment of local broadcasting problems in order to realize the fullest possibilities of the recommendations outlined.

The following is the membership of the Radio Committee: Maj. Gen. George O. Squier, War Department; Com. D. C. Bingham, U. S. N., Navy Department; W. A. Wheeler, Department of Agriculture; John W. Sutherin, Post Office Department; F. P. Guthrie, United States Shipping Board; Edwin H. Armstrong, Columbia University, New York; Dr. Alfred N. Goldsmith, Secretary, Institute of Radio Engineers; Prof. L. A. Hazeltine, Stevens Institute of Technology; John V. L. Hogan, Consulting Radio Engineer, New York; C. B. Cooper, C. B. Cooper Company, New York; Hiram Percy Maxim, President, American Radio Relay League; Prof. C. M. Jansky, University of Minnesota; A. H. Griswold, American Telegraph and Telephone Company; Leo Fitzpatrick, Radio Editor, Kansas City "Star"; D. B. Carson, Department of Commerce, Bureau of Navigation; W. D. Terrell, Department of Commerce, Bureau of Navigation; J. H. Dellinger, Department of Commerce, Bureau of Standards; L. E. Whittemore, Department of Commerce, Bureau of Standards; L. J. Heath, Treasury Department.

Note 1—Not more than six CW amateur stations to be licensed to use wave frequencies above 1050 kc/s (wave lengths below 286 meters), for communication across natural barriers.

Note 2—A class A broadcasting station is a station of sufficient power to serve an extensive territory. Fifty territorial wave frequencies approximately 10 kc/s apart are to be assigned by Department of Commerce to local areas throughout the United States without duplication. The ten such areas within each of five national zones are to have wave frequencies separated by approximately 50 kc/s.

Note 3—The 1000 and 500 kc/s (300 and 600 meter) waves are for calling and distress purposes, with a minimum of traffic.

Note 4—Mobile service on the 667 kc/s (450 meter) wave is to be stopped between 7 and 11 p. m., local standard time, and to be transferred in so far and as soon as practicable, to wave frequencies between 500 and 375 kc/s (wave lengths between 600 and 800 meters.)

"Who's Who" at the Second Radio Conference

A list of those attending the Second Radio Conference, Department of Commerce, Washington, D. C., March 20-24, 1923, follows:

Edwin H. Armstrong, Columbia Univ., New York.
Major Louis B. Bender, Signal Corps.
Commander D. C. Bingham. Navy Department.
Dr. Louis Cohen, War Department.
C. B. Cooper, New York, N. Y., Natl. Radio Chamber of Com.
Dr. Frank W. Elliott, Davenport, Ia., WOC Nat'l Broadcasters' League.
Lloyd Espenschied, New York, N. Y., A. T. & T. Co.
Harry B. Gauss, Chicago Daily News.
Paul F. Godley, Cedar Grove, N. J., Adams, Morgan Co.
Alfred N. Goldsmith, New York, N. Y., Inst. Radio Engs.
A. H. Griswold, New York, N. Y., Amer. Tel. & Teleg. Co.
John V. Hanlon, Pittsburgh, Pa., The Pittsburgh Press.
L. A. Hazeltine, Stevens Institute of Technology.
John V. L. Hogan, New York, N. Y., Engineer.
Lt. W. S. Hogg, Jr., Navy Department.
C. Francis Jenkins, Washington, D. C. (Pictures via Radio).
John M. Joy, New York, N. Y., Motion Pictures Prod. & Distributors.
Lambdin Kay, Atlanta, Ga., Atlanta Journal.
Hiram Percy Maxim, Hartford, Conn., American Radio Relay League.
Elam Miller, New York, N. Y., A. T. & T. Co.

(C. Fotograms, N. Y.)

Joseph C. Smyth, 289 86th Street, Bay Ridge, Brooklyn, N. Y., who is the winner of the World's Championship for receiving code, taking 55 words a minute on straight code work.

P. E. D. Nagle, Department of Commerce.
E. E. Plummer, Chicago, Ill., Radio Digest Illustrated.
George Schubel, New York, N. Y., Radio Broadcasting Soc. of America.
H. R. Searing, New York, N. Y., Nat'l El. Assn.
Eugene Sibley, Air Mail, Post Office Department.
John W. Sutherin, Post Office Department.
K. B. Warner, Hartford, Conn., Amer. Relay League.
W. A. Wheeler, Department of Agriculture.
Captain R. B. Woolverton, Signal Corps.
C. A. Beasley, representing W. J. Baldwin, Birmingham, Ala.
Carl H. Butman, Washington, Radio News Service.
Dr. Louis Cohen, Signal Corps.
J. C. Gilbert, Department of Agriculture.
Louis Jay Heath, Treasury Dept.
Raymond E. Huntington, Wellesley Hills, Mass.
H. P. Perrill, Office Chief U. S. Coordinator.
Harold J. Power, Medford Hillside, Mass., Amer. Radio Res. Corpn.
Maj. Gen. Geo. O. Squier, Chief Signal Officer, U. S. A.
F. P. Guthrie, Shipping Board, Radio Section.
Prof. C. M. Jansky, Univ. of Minnesota.
Leo Fitzpatrick, Kansas City Star.
D. B. Carson, Dept. of Commerce.
W. D. Terrell, Chief Radio Inspector.
J. H. Dellinger, Bureau of Standards, Washington, D. C.
L. E. Whittemore, Bureau of Standards, Washington, D. C.

Now is the Time to Build a Universal or All Wave Receiver

By Frederick J. Rumford, E.E., R.E.

IT is probably only a question of time before most of the radiophone broadcasting stations will be sending on a much higher wave length than at present. When this happens, radio fans who have the present day equipment, which is only capable of receiving from 150 meters to 500 or 600 meters as its maximum wave length, will find it necessary to load their sets with those cumbersome loading coils, which are anything but efficient. Therefore, the desirability of having a set of the kind described herewith will be apparent.

This set is efficiency in every respect, is flexible and makes it possible to receive on wave lengths from 150 to 20,000 meters. It is easily operated and uses the efficient Armstrong regenerative hook-up. The controls are few and when it is desired to receive on a higher wave length, it is only necessary to withdraw the present coils and insert the desired coils in their respective plugs.

The hook-up used is a great DX getter and DX fans who spend the later hours of the night trying to tune in long-distance stations will find this set practical.

The set the writer built was designed so that it would function properly with one WD-11 dry cell tube.

This set was designed with the idea that the prospective builder might at a later date wish to install additional amplification. Therefore, the two additional binding posts marked O. P. were placed so that with two jumper wires the set could be easily connected with the amplifier. The tuning accomplished is by varying the relation of the coils and the condensers V and VI.

Referring to the illustrations herewith, Fig. 2 shows a front view of the panel with its correct dimensions and proper symbols. Fig. 1 shows the hook-up of this set. Here is a list of the necessary parts and their estimated costs:

1	Formica panel, 9x12x¼	$3.24
1	Soft wood base, 12x9x⅜	.50
8	Binding posts at .10 each	.80
1	Single circuit jack	.75
1	Plug	1.00
1	43 plate variable condenser	4.00
1	23 plate variable condenser	3.50
2	Three-inch dials at .50 each	1.00
1	Calibrated triple coil mounting	5.00
1	Vernier rheostat, 2½ ohms resistance	1.50
1	Grid leak and condenser	1.00
1	35 turn honeycomb coil, mounted	1.50
1	50 turn honeycomb coil, mounted	2.00
1	75 turn honeycomb coil, mounted	2.50
1	WD-11 dry cell vacuum tube	6.50
1	Dry cell, 1.5 volts	.40
1	Pair 3000 ohm head phones	5.00
1	45 volt B battery	3.00
1	Complete set of antenna and ground parts	4.00
1	Phone condenser (fixed)	.25
1	Complete set of accessories, wire, screws, tubing	2.00
		$49.44

When using more than one tube an additional battery should be used for each additional tube used. The batteries should be wired in multiple.

In starting the construction of this set the builder should mark and drill all the holes that are necessary. When this has been done a good rubbing with No. 0 sandpaper and then a rubbing with a high grade linseed oil will produce an excellent finish. The base of soft wood should be given a couple of coats of a good insulating compound. After this has dried, mount the panel on one of the long sides of the base by means of several brass wood screws. Now mount the following parts upon the panel: triple coil mounting, condensers, dials, jack, rheostat and binding posts, and the little shelf at the back of the panel for the mounting of the WD-11 socket. This shelf is held in place by two brass wood or machine screws which are fastened from the front of the panel and hold the shelf rigid. The socket is then mounted upon the shelf. I advise using an adapter and the usual standard type socket as at a later date, if the builder should desire to use a radiotron tube, he easily can do so by slipping the adapter out of the socket and inserting the radiotron tube in the socket. The only other change necessary will be to use a six volt storage battery for the heating of the filament.

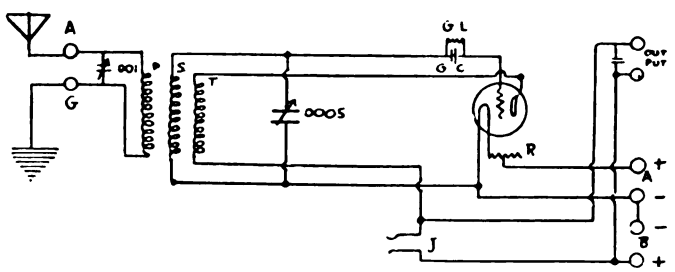

Fig. 1. Hook-up of Mr. Rumford's Universal All Wave Receiving Set.

The writer has tried another method of mounting this tube, that is the WD-11, and this method is to take the usual WD-11 socket and place up against the back of the panel and screw the brass wood screws in from the front of the panel into the socket proper which is a far better method then either of the above two.

If the builder wishes to save himself considerable work on the drilling of the panel, he can eliminate the ventilation holes on the panel proper, as the glow from the filament of the WD-11 tube when it is heated is barely visible.

The grid leak and grid condenser as well as the phone condenser can be mounted upon the base proper. The B battery can be mounted upon the base, which will help greatly to hold the set more firmly upon the operating table.

When he has the right idea from a study of the diagrams as to how the wiring ought to be done, the builder should connect a wire from the aerial binding post to one of the connections of the primary honeycomb coil, and another wire from the ground binding post to the remaining connections of the primary honeycomb coil. Now connect a wire from the aerial connections to the rotor of the 43 plate variable con-

Government Radio Messages Aggregate Millions

DURING the first quarter of the fiscal year 1923, the Naval Communications Service transmitted about 4,500,000 words, the Navy's part of which was 3,000,000, some of which necessarily was administrative, in connection with the Communications Service. It is surprising that the next largest user was the Department of Agriculture with nearly 500,000 words.

In the calendar year, the Navy handled a total of 15,768,308 words for the Government through its shore stations. Of this total, 10,884,217 were naval orders and despatches. The balance, nearly 5,000,000 words, was for other departments, both the Agricultural and War Department filing over 1,000,000 words each. All told, 16 different bureaus used the Naval radio service, including the White House and the House of Representatives.

Based on commercial rates, the Communications Service for the year ending June 30, 1922, handled for the Navy $2,721,000 worth of business and $1,040,667 for other Government departments. The Navy receives no transfer of funds or re-imbursements for the work performed for other Government departments, yet the savings are actual. The Navy has these necessary facilities and offers them to other department's use for official business. During the fiscal year 1922, the commercial work handled amounted to $277,122.42.

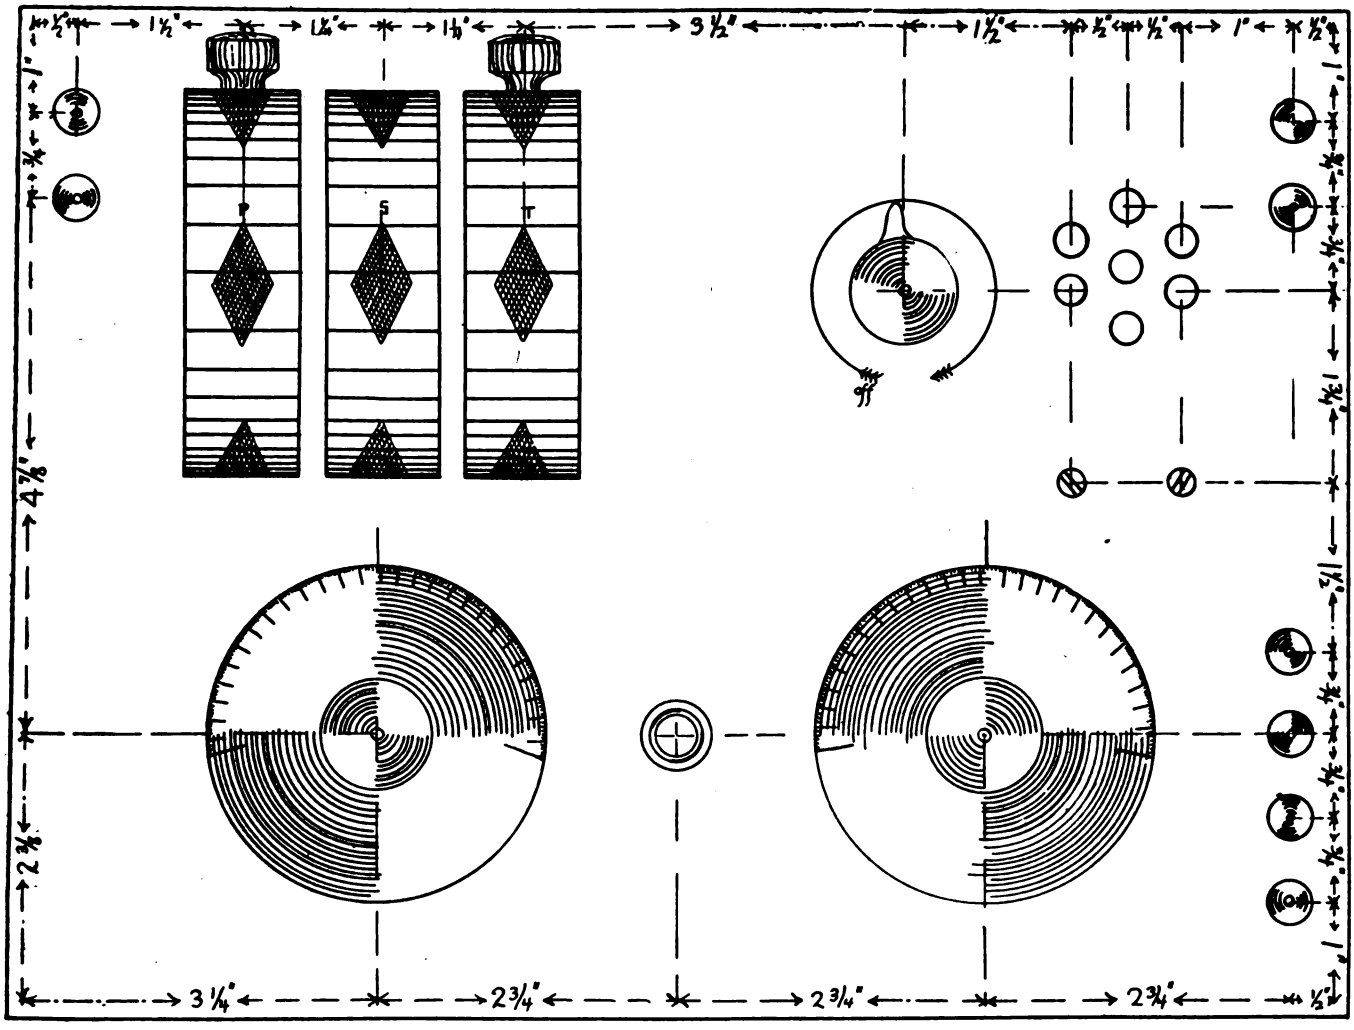

Fig. 2. Front view of panel, with correct dimensions and proper layout, used in building Mr. Rumford's Universal All Wave Receiver.

(*Continued from preceding page*)

denser, and still another wire from the ground connections to the remaining or stator connections of the 43 plate variable condenser. A wire is now run from one of the connections of the secondary honeycomb coil to one side of the grid leak and condenser, and from the remaining side to the grid post of the vacuum tube socket. The remaining side of the secondary honeycomb coil is connected with one side of the filament wire. The 23 plate variable condenser is shunted across the posts of the secondary honeycomb coil. Another wire connects with one side of the tickler honeycomb coil and connects with the plate post of the vacuum tube socket. The remaining side of the tickler honeycomb coil connects with the upper blade of the jack. The lower blade of the jack connects direct with the positive of the B battery. A wire also connects with the upper blade of the jack and with the upper output binding post. The remaining binding post connects with the positive of the B battery. Across these two binding posts is shunted a fixed phone condenser. A wire also connects with the negative side of the A battery and with one post of the rheostat. The remaining post connects with the filament post of the vacuum tube socket. The positive post of the A battery connects direct with the remaining filament post on the vacuum tube socket. There is a short jumper wire connecting the positive of the A battery to the negative of the B battery. This wiring should be done with No. 14 bare copper wire, insulated with varnished tubing.

Super Regeneration Simplified

By O. S. Kelly

MOST of the failures of the Armstrong super-regenerator, charged to technical adjustment and technical construction are wrong. The circuit is primarily an amplifier—the best developed to date—and when the cardinal points of amplification are respected, the circuit "perks."

The outstanding facts in the operation of any circuit are the limits to which the "tubes" or "bottles" can be forced, and but very little has been said about putting the circuit to work—i. e. from a non-technical standpoint.

Balance or resonance of grid and plate circuits are absolutely necessary. Any variation in these circuits requires a corresponding change in "grid bias" and plate

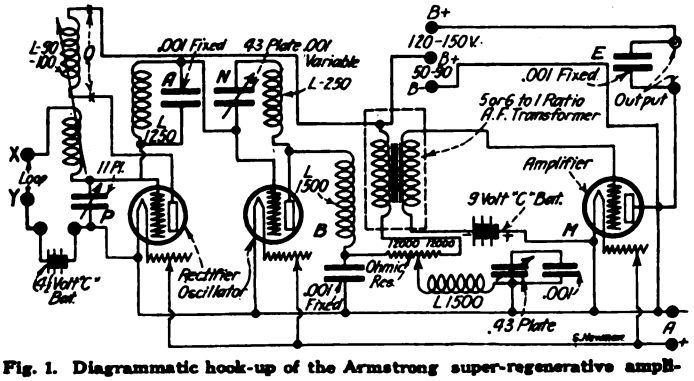

Fig. 1. Diagrammatic hook-up of the Armstrong super-regenerative amplifying circuit, as described by Mr. O. S. Kelly in the accompanying text.

battery. Example: Change the oscillator tube—you must meet the characteristic requirements of that particular grid, plate, impedance and capacity, which is readily accomplished by changing the *value* of condensers and *plate* and *grid voltage*.

The three tube circuit equipped with a filter (the 12,000 ohm two unit type) is by far the most powerful and most satisfactory. A single tube does very well, but after using some 37 circuits in different combinations, and tubes varying from the WD-11 to the U.V. 202 50 watt radiotrons, it is my opinion that for all practical purposes the U.V. 201, U.V. 201-A—the J. or 206, 216 A Western Electric or the Type C 301 A—or 301 Cunningham, is all the average amateur can use.

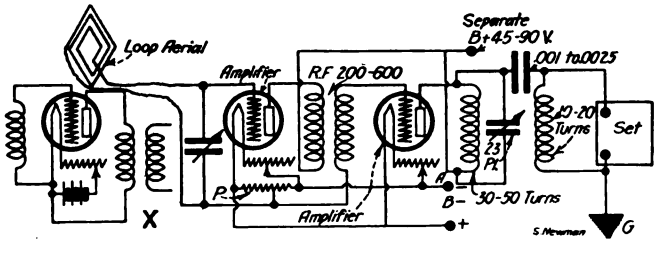

Fig. 2. Showing how to add a separate heterodyne if you wish to get more distance out of your super.

In building a super-regenerative set the first requirement is good condensers—mica is the only thing to use, and be very sure that they do not approximate the rated value.

Referring to the accompanying illustration, condensers A, B, F, E must be mica for results; and must not vary over limits +.0001 or —.0001. While it is true that the variable 43 plate at F will compensate the .001 fixed-condenser it will not control A, B and E only in a secondary measure. After completing and soldering all connections test all sockets for good contact—and absence of high voltage in filament circuit.

The following rules will tune any "sooper" of this class:

1. Turn all condensers to minimum—zero.
2. Hook up loop to input—outside turns at (X), inside to (Y).
3. Turn coupling to minimum—zero. Turn on the bulbs—light filaments bright. Hook B+ to about 80 volts—a squeal—when you vary (N).
4. Turn "Tickler"—a loud roar will greet you. If it does not and a squeal is absent, reverse connections on tickler at (X). Right here is where the average boy will quit. The roar, popping, frying and all the noise in the world is there. Anything you move makes it worse. But let her roar, and go on to number
5. Turn tickler to approximately close coupling (80° on a 90°)—(160°-170° on a 180°) and push honeycombs (if they are used) up close, ¼-⅜-inch.
6. Drop potential on the B+ taps one at a time until the roar quiets and a loud open resonant sound appears and the high frequency whistle or squeal is but faintly heard. Reverse procedure if it does not roar.
7. Now you're getting somewhere—turn tickler to minimum slowly and vary (P) until you mush signals. Slowly adjust (N), (F), (P), (Q) in order here given and you will be getting results.
8. Try out different tubes in rectifier, oscillator and amplifier sockets. Some will do much better than

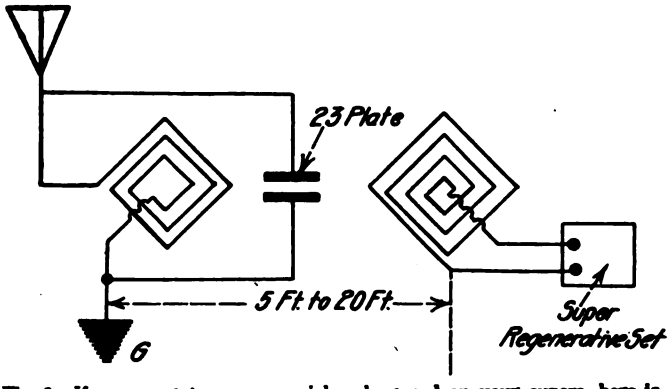

Fig. 3. If you want to use an aerial and ground on your supers, here is an idea that will help you—use two loosely coupled loops.

others and a few won't work at all only on very low plate voltage (10-15 volts).

9. Practice tuning using 8-9-10-11-12 turns on a loop 3 ft. square, or 10 turns on a loop 18 inches square. Turns on a 3 ft. loop should be spaced ⅜-½-inch. On 18 inch loop 3/16-¼-inch apart. Don't use a large loop or antenna. You are wasting time. If you just can't get that old cage or sagging flat top out of your mind use two loops, one on the antenna, one on the set. Tune the loop on the antenna. Then the one on the set. (See illustration.) Remember, the "Super" is a one job machine and it will amplify everything you let it have. It is entirely up to you.
10. Work out the peculiarities of your tubes. You will be surprised if you use "build up" or variable condensers at (A), (F) and (E). Try different plate potentials—when you get a good result mark it—then you can always return to it without guessing.

The idea has become prevalent that a super-regenerator is hard to adjust, and is no good for distance.

Cable Superseded by Radio in Navy

By Carl H. Butman

DESPATCHES for American naval vessels in the Near East are now being transmitted by radio from Annapolis and are being copied directly by vessels in the vicinity of Constantinople, with excellent results, according to Admiral Ziegemeier, director of Naval Communications.

Radio is becoming a very formidable competitor with cable service, and as far as the Navy is concerned, cables are almost obsolete. Messages are never routed by cable except to some South American countries, and if a man-of-war is there, they go by radio. Direct regular radio circuits are maintained between Washington and San Francisco and San Diego, and it is seldom that a single word is missed. Washington communicates directly with Puget Sound, and Puget Sound and San Francisco communicate every odd hour of the day.

On the Atlantic Coast, the Navy has seven main radio stations: Bar Harbor, Me.; Sayville, L. I.; Annapolis, Md.; Arlington, Va.; Cayey, P. R.; Guantanamo, Cuba and Panama, besides a large number of coastal radio stations. The station at Bar Harbor, Me., receives all official government messages from Europe, the Pacific and the fleet in the West Indies transmitting them to Washington over a leased wire. Since the fire at the Bar Harbor station, which destroyed some buildings and barracks there, the Navy has decided to turn this station into a coastal station and receive all trans-Atlantic and trans-continental traffic at Washington. Facilities in Washington for reception are being improved and it is contemplated that by the end of April, Bar Harbor will cease as the Navy's chief receiving station. This will save reconstruction of buildings there, eliminate the expense of the land line to Washington amounting to $25,000 a year, and cut the Bar Harbor personnel from 56 to 15 men.

Sayville is used as a transmittting station to the fleet and as a "standby" for Annapolis, which is the principal Atlantic Coast transmitting station to Europe and to the Pacific. Both Annapolis and Sayville are controlled from the Navy Building at Washington. Until recently the Government's method of communication with Admiral Bristol at Constantinople was from Annapolis to Paris via radio, over a leased land wire to Coblenz, Germany, thence to Vienna. From there, the message went by radio to a Naval vessel in the Mediterranean, which relayed it by radio to the Embassy at Constantinople.

Return messages were sent the same way except that the message originated on the station ship and, on this side, was received at Bar Harbor and telegraphed to the Navy Department. But during the last two months, messages have been copied direct from Annapolis by the Navy's station ship at Constantinople. Whether this can be done during the summer season remains to be seen.

NINE BROADCASTERS LICENSED

THE Department of Commerce licensed nine new broadcasters during the week ending March 24, one of which is a Class B Station located in Philadelphia. They are as follows:

Call	Station	Power
WDAH	Trinity Methodist Church, El Paso, Tex.	200 watts
KNX	Electric Lighting Supply Co., Los Angeles, Cal.	250 watts
KFFP	First Baptist Church, Moberly, Mo.	100 watts
KFEZ	American Society of Mech. Engrs., St. Louis, Mo.	500 watts
WRAL	Northern States Power Co., St. Croix Falls, Wis.	100 watts
KFHR	Star Electric & Radio Co., Seattle, Wash.	100 watts
WDAR	Lit Brothers, Philadelphia, Pa. (Class B, 400 meters)	500 watts
KFHH	McCue, Ambrose, Neah Bay, Wash.	50 watts
KFEY	Bunker Hill & Sullivan Mining & Const. Co., Kellogg, Idaho	10 watts

(*Continued from preceding page*)

This is not strictly true, for the circuits I have tested have given exceptional distance, even daylight range, for loop work. If you wish to increase your distance use two or three stages of radio frequency on the front end of a "Sooper," then reduce all B voltages as low as possible, for if you do not—it will paralyze. Too much noise for a "bottle" to handle—that's all.

Don't forget you must use tuned impedance or inductive hook-up on the last R. F. tube. (See diagram.)

When in doubt check your turns on loop and coils and go over your connections. When you have done your part the circuit will come in to more favor. These new types (U.V. 201A), (Cunningham 301A) amplifying tubes are very good (use 55-60 volts B+). You need not worry over critical filament adjustment, there is none. Just touch the filament rheostat—and hop to it. It takes time to balance up a line of tubes—three of them—but when they start working for you, you are amply repaid.

Don't fail to remember that noisy, roaring, ripping, mushy signals that increase as the tickler coupling is loosened (turned towards minimum) mean too much voltage in the B+ on the oscillator and rectifier tubes. More "C" battery (negative bias) weakens signals and causes distortion of either signals, speech, or music.

Every tube has certain internal characteristics and I have attempted to give you an average set of values that will work on most any old amplifier tube. You can refine and improve without limit.

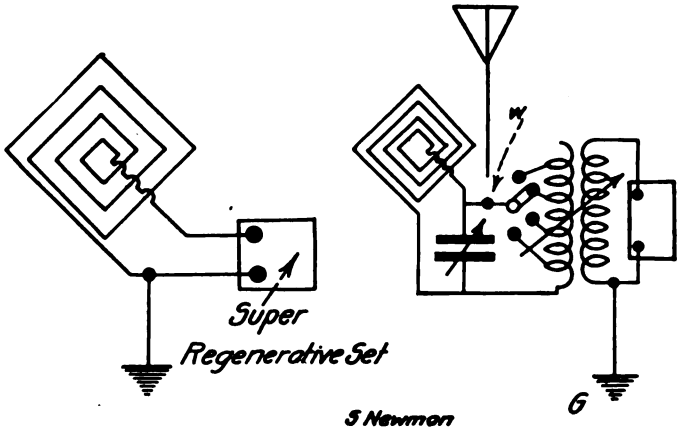

Fig. 4. If your tuning is too sharp and you want to broaden it, attach your ground as shown. If you want to add an aerial to your loop, try the method of hooking it on to W, and using a variocoupler as shown on the right.

Sidelights From the Capital Radio Conference

By Washington R. Service

WASHINGTON, D. C.—Members of the radio conference were entertained informally at dinner on Friday by Commissioner of Navigation D. B. Carson and other officials of the Radio Section. The big dining room of the Ebbitt was the scene of the first radio "get-together" in this country at which representatives of every phase of the art and industry were present. Work of re-distributing wave lengths was dropped for the moment, the business of the meeting being purely social.

* * *

Secretary Hoover believes that the universal need for more broadcasting waves will be fulfilled by the conference report. As soon as the distribution is decided upon, he will ask the president to issue an executive order assigning some of the Government waves for public use.

* * *

The plan of wave distribution presented by the radio inspectors to the radio conference was believed suitable for immediate application, whereas the compromise plan of the full committee cannot be put into operation for two or three months, it is understood, during which the already congested atmosphere may be precipitated any moment.

* * *

According to Hiram Maxim, radio makes for peace and by developing international friendships through continued and instantaneous communication between different nations, may avoid misunderstandings and eliminate the need for wars.

* * *

Composers and authors desire royalty for the use of their compositions when broadcast, Mr. Rosenthal told the conference, asking the Department of Commerce to prohibit the stations licensed from using copyrighted matter without payment of fees. But the Department replied that it might as well require licensed stations to pay rent and for the use of patented radio apparatus. Authors must go to court, it was decided.

* * *

C. Francis Jenkins, the Washington inventor of radio transmission of pictures, asked for a special transmitting wave, and predicted the practical distribution of still and moving pictures within a short time.

* * *

Every time the transferring of the 300, 450 and 600 meter waves was mentioned, either Commander Bingham, of Naval Communications, or Mr. Guthrie, Radio Director of the Shipping Board, jumped up and protested. They strove, not unsuccessfully, to preserve these waves for ship communication. The suggestion that all spark sets be removed from ships was met with the statement from naval officials that an international question was involved and several years would be necessary for such a re-adjustment. One naval officer estimated that it would cost a million and a half dollars to replace sparks on naval vessels alone.

* * *

The preservation of efficient wave lengths for use in the mobile services, such as ships and aircraft, was voiced at the conference by naval spokesmen. Fearing that the public was not included at the conference, one representative suggested the selection of a member of the radio receiving body, but Secretary Hoover said he was a fan and would protect the public interests.

* * *

The S. S. "Leviathan" will have a 750 watt, duplex telephone set when she goes into commission, the radio conferees were told by representatives of the manufacturers.

* * *

The Detroit "News" spends approximately $100,000 annually in its radio activities, Mr. Campbell of that publication stated, explaining that "good will' was the only return.

* * *

Leo Fitzpatrick, of the Kansas City "Star," official representative of the newspaper broadcasters, explained that his sheet gained only 173 subscribers due directly to radio broadcasting. But they have more than 35,000 fans who complain of the least change or delay in their schedules.

Singing into the new Thomas "glow" transmitter at Station KDKA. This transmitter has no diaphragm and is said to give perfect sound reproduction.

(C. Keystone View)
Judge John Rounds, of the Conciliation Court at St. Paul, Minn., trying a case by radio. Judge Rounds is believed to be a pioneer in legal radio.

(C. Underwood and Underwood)
Sir Basil Thomson, former director of the detective division at famous Scotland Yard, broadcasts a farewell to the United States from WJZ's Waldorf-Astoria studio, New York City.

"Chief Justice" Hoover of Radio

By Carl H. Butman

FOLLOWING in the lead of the great outdoor sport and the old favorite evening pastime, radio may take on an arbitrator. Just as Landis has come to have the "last word" in base-ball, and Hayes to write the "finale" of the movies, so Secretary Hoover may soon transmit "VA," the "30" of radio, putting an end to all arguments in the ether.

In calling the recent radio conference, Mr. Hoover offered not only to arbitrate radio disputes, but to make the necessary regulations which the Senate failed to provide. He has volunteered as a sort of foster father to this new art and industry, and hopes to clear up a threatening atmosphere. The conference in Washington, D. C., indicated whole-hearted, voluntary support by the several sections of the industry of an administration by him. It only remains for the radio public to co-operate to offset a threatened slump and remove the present broadcasting interference. Incidentally, Secretary Hoover's administration in his present capacity would save the industry the cost of a privately paid arbitrator.

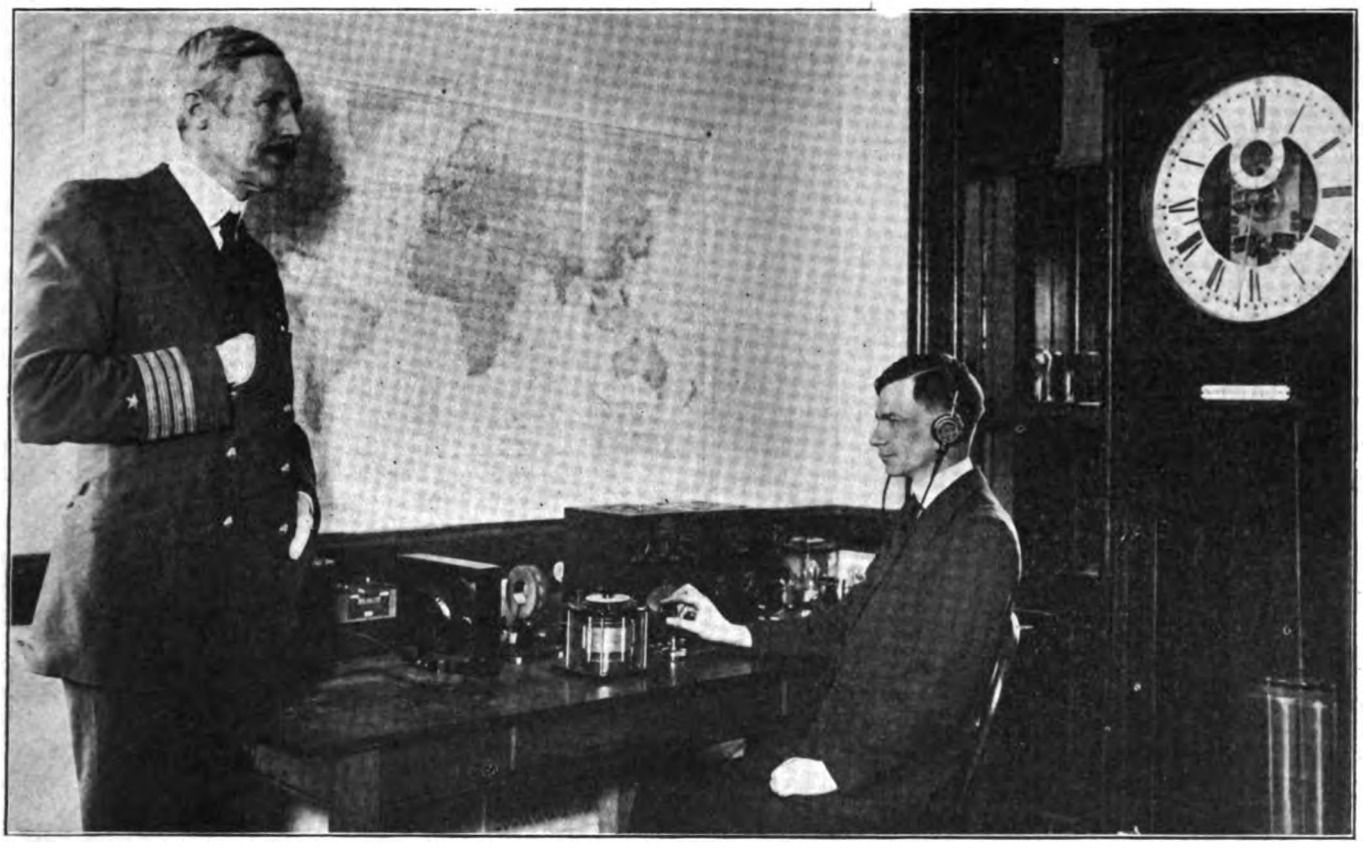
In the opinion of Major General George O. Squier, Chief Signal Officer of the Army, than whom radio has no more earnest supporter nor more generous technical contributor, the industry and public should co-operate with Hoover in his every wish.

"The failure of the Senate to pass the White Bill may be a blessing, although we all were disappointed at the time," General Squier said to the writer during the conference. The very lack of law requires a closer co-operation of the various radio activities in order to straighten out difficulties and combat interference, he explained. Co-operation is assured through the fact that manufacturers, engineers, broadcasters, commercial interests and amateurs have voluntarily subscribed to a wave length distribution and agreed to abide by such regulations as Secretary Hoover lays down as necessary. This indicates, he pointed out, how close the great radio family can be brought together when necessary.

The inventor of "wired-wireless" emphasized the great benefit to radio of a period of unhampered development and operation under voluntarily accepted regulations, instead of hard and fast laws, which could only be remedied by the passage of other laws dependent upon the action of a rather dilatory Congress. Changes in regulations found necessary during a year of such operation could be applied immediately, without reference to Congress. "The art is advancing so rapidly that we hardly know what to expect next,' General Squier said. "To-day radio is a service for the ear, but if the transmission of radio pictures— still and moving—is perfected, the eye may also be served.

"We must be ready to accept new views and apparatus at a moment's notice; not to do so would place this country in the rear instead of the van of radio progress." Since the White Bill was drafted, General Squier observed, many new phases had arisen which indicated that the bill was not entirely suitable.

"Secretary Hoover," the General said, "has practically volunteered to administer and arbitrate radio troubles for at least two years—free."



(C. Underwood and Underwood)

The Naval Observatory time signal office from which standard time is flashed daily to the country by telegraph and radio. Captain William D. McDougall, U. S. N., Superintendent of the U. S. Naval Observatory, is looking at the "original time."

The Radio Primer

For Thousands of Beginners Who Are Coming Into Radio Circles

Weekly A B C of Radio Facts and Principles Fully and Clearly Explained

By Lynn Brooks

IN diagrams, the potentiometer is shown hooked up in such a position that it is practically short circuiting the A battery. Is this not a constant drain on the battery?

The fact that the resistance of the potentiometers commonly used, is very high, and is overbalanced by the almost lack of resistance in the rest of the circuit, prevents all but a very small and negligible amount of current flowing through it, even when the rest of the circuit is turned off. In some hook-ups this is taken care of by an independent switch breaking the circuit before the current gets to the potentiometer.

* * *

Why is it that when more than two steps of audio-frequency are used that the microphonic and outside noises overbalance the signals, and ofttimes make reception impossible?

With audio-frequency amplification every noise heard in other circuits, will be amplified along with the transmitted sounds. Thus it is that a scratch which is hardly noticeable in the detector, will be amplification along with the signals and because of its low note be so troublesome when amplified that it will exclude the signals at the output of the third stage. The same applies to the inter-tube noises. It is thus seen that no more than two stages can be utilized without allowance being made for extraneous noises which cannot be filtered, and are sometimes very bothersome if more than two stages are used.

* * *

Why is it that some stations will be received fine and then a sudden change will take place and they will be all squeals and howls?

This can be caused in two ways. The first is by the interference of some nearby receiver oscillating and causing interference by re-radiating on the same wave, or it can also be caused by the carrier wave of another transmitting station suddenly interfering with that of the first, causing a beat note which will interfere.

Can the interference of the nearby receiver be eliminated in any way?

No, this cannot be eliminated as long as the oscillations from the nearby receiver, or receivers, are of sufficient power to be noticed. The person owning a sensitive receiver can often detune a fellow listener's set simply by swinging his dials and getting his receivers to squeal. This is a drawback that cannot be eliminated, and consequently has to be put up with. It is possible to heterodyne a nearby set through this re-radiation of oscillations from a receiver.

* * *

In case the builder of a single circuit receiver desires to increase the wave length range of his receiver how may he accomplish it?

The simplest manner of doing this is to incorporate a suitable mounting and a concentrated inductance in the form of a honeycomb coil of the desired range. This should be inserted in the circuit between the antenna and the apparatus.

* * *

Will this method decrease the signal strength on the lower waves?

As the honeycomb is not used when lower waves are to be received some method of shunting the coil should be utilized. This can be accomplished by inserting a single point switch in the circuit, which will short the coil when it is not in use.

* * *

What is meant by "distributed capacity"?

Distributed capacity is the capacity between adjacent turns of an inductance. Between one turn and the next, the two turns act as the plates of a condenser, with the insulation acting as the spacing or insulation of the condenser. The effect of this is to seriously broaden the wave length of the inductance, and makes close tuning hard.

* * *

Name some of the methods of keeping the distributed capacity of an inductance at a minimum.

Some of the methods of keeping the distributed capacity of an inductance at a minimum are: Do not shellac the winding; use back winding if possible, or use staggered windings, such as spider web or honeycomb. There is no way of diminishing the distributed capacity of a straight flat-wound inductance, but if a flat-wound inductance is used, and shellac is also used to hold the turns, the distributed capacity will overbalance and the wave length will be so broad that correct tuning will be almost impossible.

Radiograms

The members of the House of Commons will not be subjected to the temptation of "listening in" to jazz music or other entertainment features on the wireless telephone, to the detriment of their attention to official business, it was announced by the Postmaster General in reply to a suggestion made by a member that receiving apparatus be installed in the House. To this suggestion Sir W. Joynson-Hicks, the Postmaster General, replied that he did not think it was his duty to provide "such a counter attraction" in the Chamber of the House.

* * *

Professor Albert Einstein, of Berlin, Germany, and "relativity" fame, has erupted again with a new theory which, however, will not achieve much publicity as he says it is unintelligible to laymen. In reply to a question by a daily newspaper correspondent, Prof. Einstein is quoted as saying: "I can tell you in one sentence what it is about. It concerns the connection or relation between electricity and gravitation. It is grounded on the theoretical speculations and discoveries of the English astronomer, Eddington. It is a purely mathematical theory and, therefore, cannot be explained to a layman."

The first intercollegiate debate held by radio between New York University and Trinity College of North Carolina was broadcast one evening last week from WOR, the radio station of Bamberger & Co., Newark, N. J. Radio fans will decide who won by sending their votes to WOR. Several votes were received by telephone a few minutes after the last speaker had concluded his rebuttal.

* * *

For the second time within a week wireless telegraphy came into play when W. P. Johnson, fireman on the Fenwicks Island Shoal lightship, thirty miles southeast of Cape May, N. J., was attacked with what the captain of the lightship thought was appendicitis. The radio operator on the lightship sent out an SOS call, which was picked up by the radio station at Cape May and flashed to Captain R. C. Weightman of the coast guard cutter "Kickapoo." The message said: "Bring a physician to the lightship." Dr. V. M. d'Marcy, veteran of the World War, volunteered. The "Kickapoo" proceeded down the coast. Dr. d'Marcy was put aboard the lightship and found that the sailor's condition required an immediate operation to save his life. The "Kickapoo" then steamed under forced draft to the Delaware Breakwater, where Captain Lynch of the Lewes Coast Guard Station transferred the sick man to the hospital. Word was received at Cape May by radio that the operation was a success.

Radio and the Woman

By Crystal D. Tector

FRIEND Husband the other day came home real early and when questioned by yours truly concerning the reason, said that he was going to try a new aerial and the Beverage System as he heard that a man in town had had such wonderful results. So he put on his working clothes (a pair of torn and disreputable overalls, sneakers and a cap that he wears when he "puts the car in order") and started in climbing around the roof. I was inside making his favorite layer cake and paid no attention, as he generally gets an idea once in a while and then you can't do anything with him until he is either tired out or so disgusted with it that he refuses to work on it any more. An hour passed and no sign of friend husband, outside of a lot of noise on the roof. Suddenly, a yell and I saw a bunch of shingles come sliding down to the yard with a bang. I rushed outside and found F. H. very scared hanging on by the edge of his trousers to the roof, upside down. Perfectly safe, but looking ridiculous. After getting a ladder, and sending for the town builder to put a new roof on, he vehemently swore that "The next time that I try to put an aerial on the roof, I am going to stay on the ground to do it. Imagine what Dr. —— and his wife next door must have thought! I looked perfectly ridiculous." "That is all right," say I, "but I think that the Doctor must have been disappointed when you arrived safe and sound. Well, such is life—it's filled with disappointments."

* * *

FRIEND HUSBAND'S boss gets a "soft spot" every once in a while, and sort of "weeps for the world" according to hubby, and then simply can't hear any sad story. Last week was one of his "conscience" periods, and he heard of a blind asylum which needed help. So he took Friend Husband into his plans and thought that besides giving money he would donate a talking machine for their entertainment. "Talking machine! Why don't you be up-to-date and get them a radio receiver? It will give them more fun and it doesn't need so much care," said my hubby. "By Jove, you're right! Go out and get them one right away, bring it back and we'll take it up. You know more about those things than I do, so draw a check and go ahead." Well, friend husband went out and bought a nice little loop set, batteries and all, and brought it in to let the boss see it. He said the boss decided that he would take that one home to play with and made him go and buy another for the donation. Well, it's the old story. You can remain immune just so long, but when you fall you fall hard and quick. That's just the way with radio fans—they don't realize what they are missing until the little innocuous bug bites them and then they're gone for good.

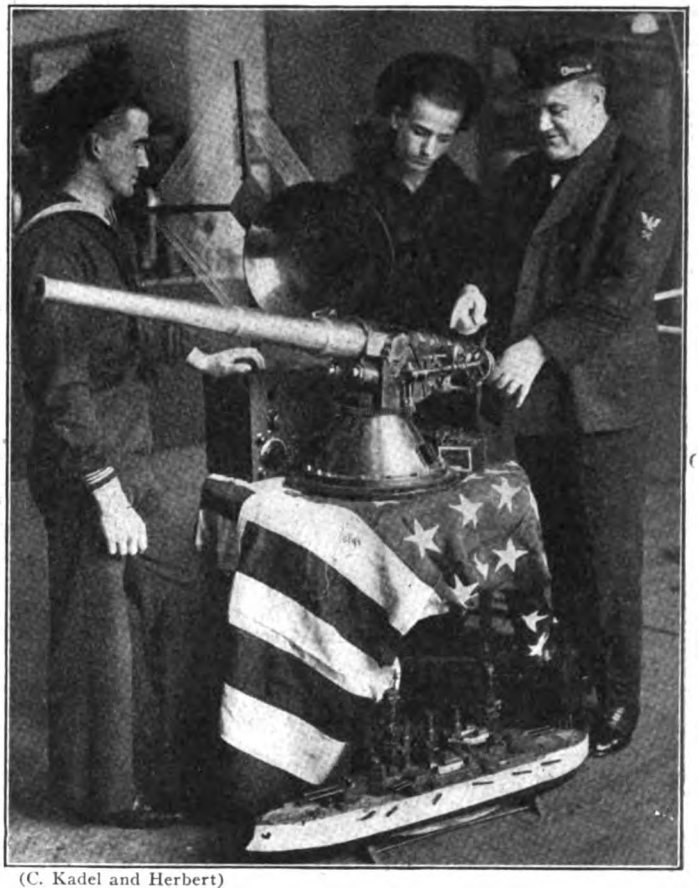
* * *

Girls, the editor asked me to publish a paragraph this week asking why some of the women don't write in for the DX Nite Owls. Surely some of us must be able to at least beat some of those "radio golf hounds." I know that my record is a mean one to look at, and I am going to put it in next week to start it along. Now who is going to follow me up?

* * *

Some people are so impossible that it makes me believe that a babe in arms has more common sense than they have. The other evening the phone rang and my husband's friend, who prides himself upon the fact that he is really handy and besides that calls himself an electrician, asked if he could bring his set over and show it to us, that something was wrong and all his bulbs had lit up bright and then gone out, and he couldn't light them up any more. When he came over he said that he had put in a new set of batteries and connected them up and then the bulbs had gone out. Well, he had connected the B batteries to the same posts as the storage battery, and consequently "blown" all his bulbs. Well, we could not make him understand why he shouldn't have done it, and his constant argument was, "Well, isn't it a battery, just the same? Why should I have to buy new bulbs just because I connected them wrong?" I wonder if his wife ever asks him to post a letter?

Radio Lecture Explained By Gun Model



(C. Kadel and Herbert)

A lecture on gunnery is being broadcast. The lecture is received on a loop receiver, and by the use of a small model a demonstration is being given to future gun pointers. The illustration shows Chief Petty Officer A. L. Whalen explaining the lecture to R. P. Smith and M. O. Trunnel, assisted by the radio receiver in the background.

* * *

Did you hear Romeo and Juliet broadcast last week? I was having the grandest time listening in to it, when F. H. woke up out of his after dinner snooze, looked at me a second, and then with a wry face, said: "Turn that Bla Bla off! It reminds me of the first time that I sat in the moonlight without my hat, and felt foolish." Well, I like that! He told me that I was the "one and only." Well, I've got him now, and that's all that counts.

Answers to Readers

ENCLOSED find a diagram showing my present set, which is a regenerative with two steps of amplification. Kindly publish or refer me to where I can obtain a hook-up of a step of radio frequency to go before the detector.—B. L. Bailie, 7720 Plymouth Road, Detroit, Mich.

We refer you to RADIO WORLD for February 24, 1923, where you will find the diagram you require, in answer to a similar inquiry by Mr. Beckhouse. You state that you have two stages of audio frequency, while the diagram has only one. This is of little consequence, as you will not have to change your present amplifer unit hook-up at all, it only being necessary to change the circuit in front of the detector, which is simple.

* * *

1. Does it matter if the antenna is allowed to sag in the center? Would the signals be any stronger if the wire were stretched tight?

2. My antenna runs through the branches of trees. Would this cause the signals to fade out? The batteries are all new, and the set is a Westinghouse Type RC.

3. Is it necessary to have the lead in end of the antenna lower than the other end of the antenna, or should they be the same height?—Chas. E. Stevens, M. D., Bessemer, Michigan.

1. It will not affect the strength of the signals if the wire is sagged.

2. We cannot understand how the antenna running through the branches of the trees would cause the signals to fade, but advise you, however, to place your antenna where it will not have to run in this fashion, as experiments have proved that trees have the power to absorb energy and will therefore tend to decrease that received signal strength. Examine your ground connection and see that your antenna is well insulated. The fading might possibly be from the antenna swinging against the tree and then swinging back again.

3. It is not necessary to have the lead in end of the antenna lower than the other end. They may both be the same height.

* * *

1. What size wire and how many turns should be used on the coils described by F. J. Rumford in his article on the Satterlee circuit?

2. What condensers should be used in the antenna and secondary circuits?

3. Do two separate wires run from the antenna binding posts to each of the coils separately, then through the coils and finally from the end of the coils to the ground post; or are the coils connected in series to the ground?—George J. Schretter, 200 Tyson Street, New Brighton, Staten Island, N. Y.

1. These coils are wound pancake form, and consist of 100 turns each for the outside coils. They should be wound with about No. 22 DC wire.

2. The condensers used are .0005 in the primary and .001 in the secondary circuit.

3. These coils are connected in such a manner that they are in parallel, which is exactly as the diagram has them. The selectivity of this set is due to this. Also, there is no antenna needed when a ground is used, or vice versa. If you use an antenna you do not need a ground, and if you use a ground you will not need an antenna. In nearby reception over a distance of 25-40 miles no antenna or ground is necessary, the set itself being all that is required for good reception.

* * *

1. Is the WD-11 tube of any use for radio frequency?

2. In the circuit described by Mr. P. F. Albright, what principle is used? The circuit doesn't appear to be regenerative although the results seem to show that he is getting regeneration.

3. What is the Ultra Audion circuit or receiver?

4. Would anything be gained by using a tube detector instead of the crystal in the three tube reflex circuit published on March 3 by W. S. Thompson?

5. How many stages of radio frequency would be necessary to secure the same audibility that I now get through regeneration?

6. Using a fixed inductance of about 70 turns, on a 2½-inch tube, what should be the wave length range using a .0005 variable condenser, also using a .001 condenser?

7. How is the tuning governed in the set asked about in Question 2?—A. Leslie, Twin Falls, Idaho, P. O. Box 1056.

1. While the WD-11 tube can be used for radio frequency, it is not advisable because of the fact that not sufficient volume will be noticed in the strength of the signals. These tubes were not made for radio frequency, and should not be used for it. They will work, but not satisfactorily.

2. Regeneration is the principle, getting back-coupling from the plate much the same as in all the single circuit regenerative circuits.

3. The Ultra Audion method of reception, was discovered by Dr. Lee de Forest, and embodies the principle of directly coupling one side of the secondary circuit to the plate.

4. In the circuit you mention, you would of course gain some volume of sound but this would be discounted by the distortion which would be noticed. Crystal detection is ideal, and should be used in reflex circuits whenever possible.

5. This is a blind question and cannot very well be answered, as the amount of volume varies with different constants such as kind of tube, transformer, etc. But you will be disappointed if you do not at least use two stages, as with one stage no appreciable difference in distance or clearness can be noticed.

6. The wave length range of this coil when used in parallel with the .0005 condenser will be approximately 300-750 meters and with the .001 condenser it will be about 300-1400 meters. This is of course an approximate calculation, and does not take into consideration the actual length of the antenna used.

7. The tuning is accomplished by means of the rotor of the double wound coupler, the construction of which is shown in the sketch.

* * *

1. Compared with the WD-11 tubes, how are the "Midget Peanut" 3 volt tubes?

2. Can these tubes be used with Ortherus Gordon hook-up?

3. Will these tubes stand 45 volts on the plate?—Edgar L. Miller, 2353 Payne Street, Louisville, Ky.

1. We do not compare various makes of competive apparatus in this column; so we cannot, therefore give you the information that you desire on this point.

2-3. These tubes can be used in the Gordon circuit and they will stand the voltage you name, although it is not necessary to use 45 volts on the plate to get them to work their best. Harm is done by using more plate voltage than is necessary and by burning the filament high, than any other method of disuse. The wise user will operate his tubes on as low plate and filament voltage as he can efficiently.

* * *

Where can I obtain blueprints of circuits described in your issues by W. S. Thompson and Frederick J. Rumford?—K. H. Pettit, care Choctaw Telephone Co., Soper, Okla.

We do not handle blueprints of these circuits, but if you will communicate with the writers you mention, through RADIO WORLD, we will see that the letters are forwarded.

* * *

Give me a hook-up for the following apparatus: 23-plate condenser, variometer, loading coil, switch, tube, etc.—Joseph Honnors, 134 Wheeler street, Gloucester, Mass.

We refer you to RADIO WORLD for February 17, 1923, where you will find a circuit such as you desire on page 11 under the heading "A Hook-Up That Is a Wonder," by George W. May.

* * *

Where can I obtain information on the reflex circuit published in RADIO WORLD for February 17, 1923, by C. White?—K. L. Hathaway, 3157 Maple street, San Diego, Cal.

If you will address a letter to the writer of the article in care of RADIO WORLD we will see that it is forwarded to him.

Assistant Examiners Wanted for the Patent Office

THE United States Civil Service Commission announces that an open competitive examination will be held throughout the country on May 9, 10, and 11. It is to fill vacancies in the Patent Office at Washington, D. C., at an entrance salary of $1,500 a year, plus the increase of $20 a month granted by Congress. There is provision for promotion to positions paying as high as $3,900 a year. In addition to present vacancies, 43 new positions are authorized, effective July 1.

Competitors will be examined in the subjects of physics, mechanical drawing, technics, mathematics, language (French and German), and optional subject. Applicants must select one of the following optional subjects: Electro-chemistry, general chemistry, or chemical, civil, electrical and mechanical engineering.

On account of the urgent need for assistant examiners, the examination papers will be rated and certification of eligibles made within the shortest possible time after holding the examination.

Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or the secretary of the Board of U. S. civil service examiners at the post office or custom house in any city.

Business Will Continue to Be Good

THE recovery of business from the depression of 1921 has proceeded normally, in spite of the European unsettlement, and good business may be expected throughout 1923, according to a report made public by the Harvard Economic Service, at Cambridge, Mass., last week. The outlook for the rest of this year is further expansion of business, firm or higher commodity prices, and firm or higher money rates.

United States Stations Heard in Cuba

Frank H. Jones, a radio enthusiast of Tuinucu, Cuba, is well-known in the radio world for this enthusiast has brought in nearly every broadcasting station in the United States. Each night he listens-in regularly to such stations as KDKA, the Westinghouse station at East Pittsburgh, WJZ, the Westinghouse-Radio Corporation station at Newark, N. J., Davenport, Iowa, Chicago, or any of the so-called big stations.

Recently Mr. Jones wrote to the Westinghouse Electric International Company's Cuban office in Havana telling how he obtains such good radio records.

His letter is so interesting that excerpts from it will be worth while reading for any amateur:

"With the R. C. set (the Westinghouse single circuit tuner with two stages), on the detector tube alone I have heard over 100 United States, Cuban and Porto Rican radio telephone stations. My radio golf score now stands at over 100,000 miles. Ordinarily I use an antenna with the R. C. set although with a four foot loop, not shown in the photograph, connected with one side to the antenna post of the R. C. set and the other end free and using a ground, I have heard KDKA, WGY, and other stations with the detector tube alone.

"The set underneath the R. C. I made myself. The four dials at the left are various condensers and tapped inductance. Knobs in center are attached to three radio frequency amplifier 201 tubes and two potentiometers. Towards the right is a complete three circuit regenerative tuner with variocouplers, grid variometer and plate variometer; then the detector tube and its rheostat and phone jack.

"In this set I can use (by throwing various switches inside the cover of the set) the following:

"(1) Antenna with three stages radio frequency amplification and detector.

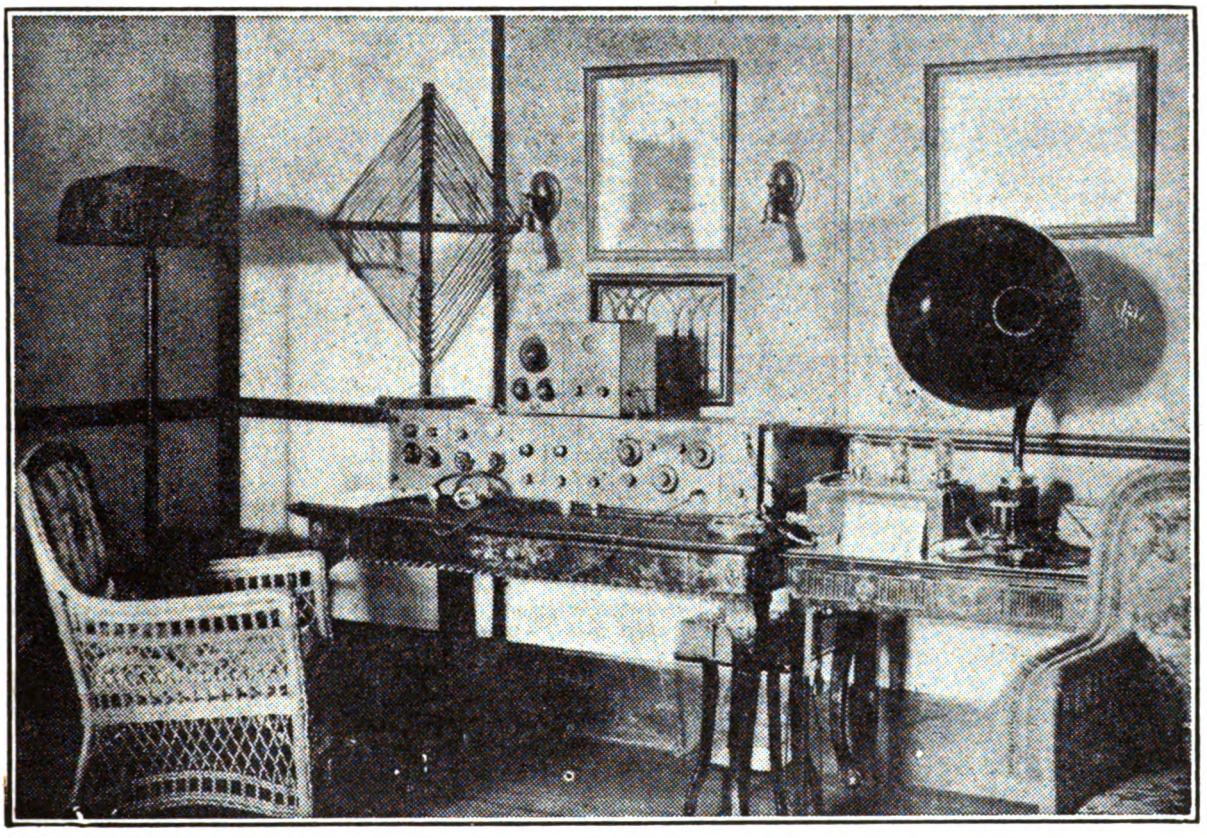
"(2) Antenna with triple coil honeycombs inside set with three stages radio frequency amplification and detector.

"(3) Antenna and three circuit regenerative receiver and detector.

"(4) Antenna and three stages of radio frequency amplification and regenerative circuit combined.

"(5) Eighteen inch loop shown on top of set with three stages of radio frequency amplification and detector.

"Inside the set is an audio frequency transformer for coupling the detector tube to the magnavox amplifier."



Frank H. Jones' radio receiving station at Tuinucu Cuba, which regularly picks up United States broadcasters.

Radio Club of Brooklyn, N. Y.

THE Radio Club of Brooklyn, N. Y., the oldest and foremost radio club in that city, is now well in its eighth year of progress. It is the representative radio club of Brooklyn, and an important factor in Brooklyn's amateur radio. It numbers among its membership many famous in radio engineering and amateur DX.

At its last meeting plans were presented for the club's annual affair. It promises to be a merry occasion, and a good time is assured all who attend. Further announcements regarding this will be made later.

All complaints of amateur interference should be addressed to this club, since it has been authorized by the Executive Radio Council to take care of such affairs. These complaints should comprise Brooklyn only. Matters in other cities should be addressed to the local clubs.

Meetings are held the second and fourth Fridays of the month at 2211 Bedford avenue, near Church avenue, at 8:30 p. m. A cordial invitation is extended those interested in amateur radio to visit the club. Communications should be addressed to the secretary, D. F. Kirchick, 409 Osborne street, Brooklyn, N. Y.

Beware Buying This Stolen Radio Apparatus!

THE Edward J. Goetz Co., 47 Cambridge Building, Cincinnati, Ohio, requests RADIO WORLD to notify the industry that the company's warehouse, at 2409 Harris avenue, Norwood, Ohio, was burglarized recently, and the following merchandise stolen: One F. R. L. super set, one Firth Vocatone, one Edgco de luxe set, one Magnavox, two Bristol loud-speakers, and a considerable number of small radio parts.

Dealers are requested to be on guard, and if any of the merchandise mentioned is offered to them to notify their local police authorities, as well as the owner of the goods.

WGY Spells Schenectady, N. Y.

CORRESPONDENTS of WGY, the General Electric Company's radio broadcasting station at Schenectady, N. Y., frequently have trouble in spelling the name of the city. English radio fans generally address "General Electric Company, New York," and make no attempt to spell "Schenectady." A five-year-old boy living at North Hoosick, Mass., has happily solved the problem according to the following which appeared in a Massachusetts newspaper:

"Fred Stevens, of North Hoosick, picked up the five-year-old son of Ira Fisk, and gave the boy a lift on the way to school. The juvenile Fisk is noted for his brightness and Mr. Stevens began a quiz. The youngster, of course, spelled 'cat' and things of that kind without any trouble, but Mr. Stevens thought he put a poser when he asked the boy if he could spell 'Schenectady.' 'Sure,' was the prompt response, 'WGY.'"

Latest Radio Patents

Radio Transmission Control System

No. 1,447,773: Patented March 6, 1923. Patentees: Lloyd Espenschied, Queens, N. Y., and Ralph Bown, East Orange, N. J.

This invention relates to radio signaling, and more particularly to the control of the level of transmission in such signaling. While it will be described as applied especially to radio telephony for the reason

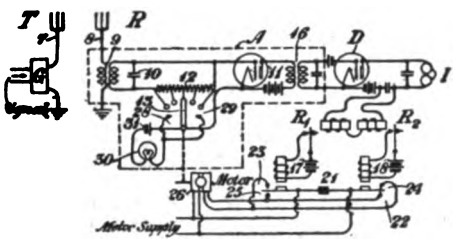

Diagram of Espenschied and Bown's Radio Transmission Control System.

that the need is greatest in that field, it is to be understood that it may be applied equally well to telegraphy, or the transmission of any other signals. Its object is particularly to improve the constancy of transmission characteristics in radio communication.

In radio signaling there are present to an enormous extent variations in the transmission characteristics which render it difficult to obtain satisfactory signal conditions and which result, among other things, in large fluctuations in the volume of a telephone or other message being transmitted. These variations may be due to such well known phenomena as "fading away" or to differences in day and night signaling. Or, again, they may be due to changes in the apparatus, either at the sending or receiving stations. If, in long-distance radio transmission, repeater stations are used further possibilities for variations enter. These variations may be sudden or slow, depending on their origin, but in any case detract materially from the effectiveness of radio communication.

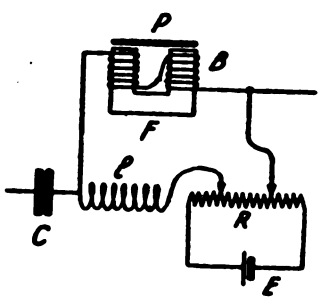
In our invention we propose to overcome the effect of these variations by providing compensating means, preferably automatic, and in general, to accomplish this we virtually set aside a signal channel which may be considered as a "pilot" channel over which shall come information as to the transmission character of the ether path through which the signals come.

Radio Receiving System

No. 1,447,793: Patented March 6, 1923. Patentee: Marius Latour, Paris, France

The present invention relates to improvements in circuit arrangements of radiotelegraphic receiving stations for the purpose of increasing the sensitiveness of the receiving and making possible the application of the principle of heterodyne action in the reception of Hertzian waves.

As well known, in the case of crystal detectors, the rectified portion of the current is proportional to the square of the alternating potential v acting on the circuit comprising the detector. On the other hand, if a potential V of a slightly different period is introduced into the receiving circuit it is found that the sensitiveness of the receiving increased with the potential V up to a certain limit.



Latour's Improved Radio Receiving System.

It has been found advisable to increase V until the law of the square no longer holds good and up to a point beginning at which the rectified portion of the current is simply proportional to the potential applied to the detector. The increasing of V above this value will be useless.

The only difficulty that will be encountered in increasing V will be the presence of a permanent rectified current in the telephone. This permanent current will cause the permanent attraction of the diaphragm that may cause a lowering of the sensitiveness of the telephone. As a result of this, beginning with a certain value for V, the increase in sensitiveness corresponding to the increase of V will be concealed.

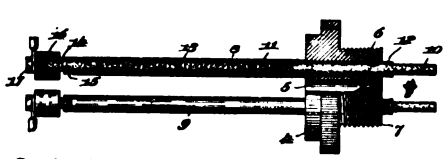
This disadvantage may be remedied in the following simple manner:

A simple expedient is to use telephones provided with magnets of lower magnetization. The permanent rectified current would only add its effect to the magnetism of the magnet to supplement its insufficiency and produce the necessary permanent induction under the diaphragm. It is also conceivable that we may operate without a permanent magnet and use only the rectified current for producing the necessary permanent induction.

Flexible Electrode

No. 1,447,357: Patented March 6, 1923. Patentee: David R. Price, Newtonville, Mass.

This invention relates to an improved non-corrosive and flexible electrode. While adapted for general use wherever



Sectional View of Price's Flexible Electrode.

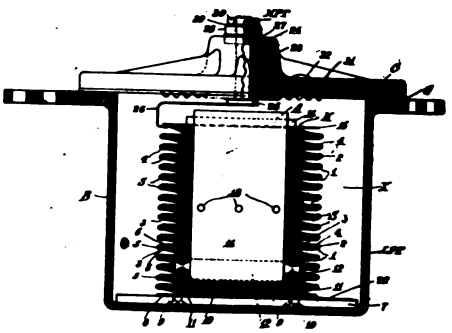
electrodes of such characteristics may be desirable, it is of particular application in connection with the device for determining the liquid level in storage batteries which I have described and claimed in application Serial No. 358,495, filed on even date herewith. In the construction of an electrode for use in connection with storage batteries or the like, the electrode must be constructed of material inert in sulphuric acid or in similar electrolytes. Storage batteries give off fumes from the electrolyte, especially during the charging of the battery, which fumes are highly corrosive in action so that it is essential that the connection of the usual metallic conductor to the electrode take place at a point relatively remote from the point of discharge of the fumes. In order to carry out this last requirement it is highly desirable that the electrode itself be flexible since storage batteries are very generally located in restricted spaces. A solid electrode extending away from the battery proper would be easily broken and therefore unreliable.

It is an object of my invention to provide a flexible electrode formed of material which is normally inert in sulphuric acid or similar electrolytes and to provide such an electrode which may be easily and cheaply constructed of material which may be readily obtained. It is also an object of the present invention to provide a new and improved method of forming and assembling such electrodes.

Electrical Condenser

No. 1,446,850: Patented Feb. 27, 1923. Patentee: Byron Macpherson, Roxbury, Mass.

THIS invention relates to improvements in electrical condensers of the plate or sheet type, especially of the type wherein the condenser is divided into sections and the sections connected in series for high potential service, although not limited to series condensers; and the invention consists of certain improvements in the means for clamping the stack. This application is a continuation in part of my application Serial No. 301,498, filed June 3, 1919.



Sectional View of Macpherson's Electrical Condenser.

My invention is especially applicable to the type of stack in which the two ends are at a difference of potential and is embodied preferably as an insulating clamp; that is, a clamp in which the two ends of the stack are connected by a member comprising insulating material. An advantage of my form of clamp resides in the fact that the capacity of the condenser remains constant with time and use.

This clamp in particular comprises metallic end blocks or members engaging the ends of the stack, and a flexible band of insulating material connecting the members and drawing the same into clamping relation against the ends of the stack, the ends of the stack being at high potential differences.

Improved Dial Knob

No. 1,445,812: Patented Feb. 20, 1923. Patentee: Charles P. Whitall, Longmeadow, Mass.

THIS invention relates to dial knobs such as are used for adjusting various rotatable parts of radio apparatus. The invention has for its object to provide an improved molded dial knob of light but rugged construction and of distinctive and pleasing appearance and one which is particularly well adapted for economical quantity production. The invention consists in the novel and advantageous features employed.

The DX Nite Owls

THE Editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

Fine Stuff! Send 'Em in Men, Send 'Em in!

From Maxwell Davidson, Jr., Lawrence, L. I.

BEING a constant reader of RADIO WORLD and buying it weekly, I have noticed the column devoted to the DX'ers. I have not noticed many amateurs listed, however. I am sending my list for the period of time I have had my Grebe CR-9 (four months), and, if it is not imposing, I would like particularly to see my list published. I find a 43-plate variable condenser in series with my ground aids selectivity.

Local and DX—WJZ, WOR, WBS, WBAN, WAAM, WIP, WOO, WFI, KDKA, WEAF, WHAS, WSB, WHN, WGI, WGF, WGL, WGM, WGY, WOC, KYW, WHAZ, WBZ, WHK, PWX, WWJ, WHB, WDAP, WPI, WMAF, NOF, NAA, NAH, CFCA, WLW, KSO, WBAP, WPA (Texas), WBT, WCAU, KOP, WQAA, WIAO, WLK, WNAC, WWL (Louisiana), WDAJ, WLAG, WRW, WOH, WHAM, WCAE, WUP, WJAX, WEAO, WMAK, WDAF, WSY, WMAQ, WQAO, WMC, WIAR, WOAX, WDAL (Florida), WWAD, CFCA, CHYC, CKAC, WAAP (Kansas).

AM—IXB, 2AYZ, 2BUM, 2EL, 2PB, 2CLO, 2BQU, 2BY, 2AZY, 2ZL, 2BDF, 2BWU, 2ACY, 2OE, 2AFM, 2BUA, 2ABA, 2ACB, 2CPD, 1BKA, 1RI, 1BEF, 2ABD, 2AWL, 2CPW.

Grand total, 93. Can prove all with data and date. Would like to communicate with any Grebe 9 owner.

* * *

"Out Where the West Is"

From Pat Ewing, Hardin, Montana.

I AM a subscriber to RADIO WORLD and enjoy the DX Nite Owls very much. Here are some of the stations I get on a detector tube: Atlanta, Havana, New York, Chicago, San Francisco and Canada. We all get 1,500 miles or better out here (where the West is) every night. Any fan that does not have a loud-speaker might try this one: Put phones in coffee cups and note the results. I have a house full of music every night with detector tube, 2,000-ohm, head set and coffee cups. Try it.

* * *

Gotta Show Us Y'Know!

From H. R. Graf, Jackson, Mich.

AS a reader of the RADIO WORLD and especially interested in the "DX Nite Owls" records, I am sending my record of 24 stations in one evening from 7:00 to 9:00 o'clock P. M.

They are as follows: St. Louis, KSD; Chicago, KYW; Detroit, WWJ; Schenectady, WGY; Pittsburgh, KDKA; Kansas City, WHB; Newark, WJZ; Memphis, WMC; Davenport, WOC; Louisville, WHAS; Paducah, WIAP; Birmingham, WSY; Detroit, WCX; Fort Worth, WBAP; Pittsburgh, WCAE; Winnipeg, Ont., CJCG; College Park, WDAJ; New York, WEAF; Minneapolis, WLAG; Lockport, WMAK; Chicago, WMAQ; Boston, WNAC; Jefferson City, WOS; Atlanta, WSB. In all I have heard 75 stations. The farthest is Honolulu, Hawaii, KDYX, about 4,800 miles. I am using a tickler circuit and one-stage of audio-frequency, which I constructed.

* * *

Auburn Come in QSA

From Ora Lyons, 803 Main St., Auburn, Ind.

I READ in a recent issue of RADIO WORLD an article relative to the distance of a single-circuit detector tube set. I am using the above circuit and receive the Los Angeles, Cal., station, KHJ; Winnipeg, Canada, CJG; Dallas, Texas, WFAA; Fort Worth, Texas, WBAP; Newark, N. J., WOR; Atlanta, Ga., WGM; Havana, Cuba, PWX, as well as several intermediate stations. Mr. Guy Fitzsimmons constructed the hook-up which I used in tuning in for the above named stations. Mr. Fitzsimmons lives in Auburn, Ind. My aerial is 18 feet high and 50 feet long.

* * *

California Registers WOW!!

From Earl Kauffman, Clovis, Calif.

I NOTE with amusement the challenges of Mr. Lindstrom, of Baraboo, Wis., regarding his hearing voice and music from all over the United States. Why shouldn't he? He is in an ideal location, and time is in his favor. If Mike Podhorn (old tinhorn), of Wood River, Ill., isn't getting like results from his ideal location would advise him to discard his expensive set and make himself a *good* one.

Time is against us for receiving eastern stations. However, we hear WLW, WGM, KDYL, KZN, WDAF, WOZ, WOAJ, WCAT, KSD and PWZ Wednesday and Saturday nights from 6 to 7:30 p. m., Pacific Time. This on one-step audio-frequency. Also want it understood there is nothing to patent about this set, but it has a vernier condenser, without which no one can expect to tune in anything and know what he is going to tune in. Use a spider-web coil for a secondary in a Remler style, tapped vario-coupler. Two sets of head phones are used, and can substantiate every station named by reliable witnesses.

* * *

One WD-11 Without Amplification

From O. E. Slaybrough, 2853 Shriver Ave., Indianapolis, Ind.

I HAVE been reading the records of the "DX Nite Owls" in RADIO WORLD and I am sending my list for the night of March 9. All stations were received on a single-circuit regenerative set, built by myself using one WD-11 tube without amplification.

WLAG, Minneapolis, 500 miles; WOC, Davenport, Ia., 285; WCK and KSD, St. Louis, Mo., 260; WIAR, Paducah, Ky., 270; WGY, Schenectady, 685; WBAO, Dallas, Texas, 805; WDAJ, College Park, Ga., 355; WSB and WGM, Atlanta, Ga., 345; WOS, Jefferson City, Mo., 345; WSY, Birmingham, Ala., 460; WDAF, Kansas City, 490; WMC, Memphis, Tenn., 385; KDKA, Pittsburgh, Pa., 345; WMAQ, WDAP and KYW, Chicago, Ill., 200; WAAP, Wichita, Kan., 635; WBAA, West Lafayette, Ind., 60. KFI and KPK, Los Angeles, Cal., 1,895; KFDL, Denver, Col., 1,005 miles.

Why Magnavox *is* the Reproducer Supreme

OFFICIAL tests with the oscillograph prove that the Magnavox electro-dynamic receiver reproduces incoming wave forms with maximum accuracy.

The Magnavox can be used with any receiving set—the better the set, the more Magnavox can do for you.

When you purchase a Magnavox you possess an instrument of the very highest quality and efficiency.

R2 Magnavox Radio with 18-inch horn
(as illustrated)

This instrument is intended for those who wish the utmost in amplifying power; for clubs, hotels, dance halls, large audiences, etc. It requires only .6 of an ampere for the field. Price, $60.00

R3 Magnavox Radio with 14-inch horn

The ideal instrument for use in homes, offices, amateur stations, etc. Same in principle and construction as Type R2. Price, $35.00

Model C Magnavox Power Amplifier

For use with the Magnavox Radio and insures getting the largest possible power input.

2-stage, $55.00
3-stage, $75.00

Magnavox products can be had of good dealers everywhere.

Congratulations from a Competent Authority

Editor, RADIO WORLD:

Upon the occasion of your special anniversary number of RADIO WORLD, I am happy in the opportunity to congratulate you on the tremendous strides which your publication has made in its first year.

Your own unfailing courage and the energy and devotion of your associates have given us a weekly radio publication that many thousands of us in radio deeply appreciate.

You have the best wishes of everyone of us in the Sleeper Radio Corporation for a big prosperous new year and many years like it to come.

Cordially yours,
GORDON C. SLEEPER.

New York,
March 28, 1923.

New Nantucket Lightship to Have Radio

THE present Nantucket, Mass., lightship will be displaced by the latest and best equipped lightship in the service about the first of June, according to the Commissioner of Lighthouses. Inbound transatlantic liners will be greatly aided against the dangers of fogs and the treacherous shoals in these waters by the installation of a radio signal set capable of communicating with ships within a hundred miles of the shoals. The present lightship has no radio service and during foggy weather the light is not discernible. When the radio signaling apparatus on the new lightship is installed inbound liners will be able to get their bearings in all kinds of weather.

Secretaries of Radio Clubs, Attention!

THE secretaries of radio clubs throughout the United States are requested to send to RADIO WORLD any news of interest to other radio enthusiasts which may come to their notice at club meetings or elsewhere. RADIO WORLD desires to co-operate to the fullest extent with clubs and other organizations in all their progressive efforts.

RADIO WORLD SELLS FAST IN CALIFORNIA
RADIO WORLD is the best of them all. Your publication is all sold out on the local newsstands almost as soon as they arrive here.

Coming Events

PERMANENT RADIO FAIR FOR BUYERS, Hotel Imperial, New York City. Open from September, 1922, to May, 1923.

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits. Atlantic City, N. J., June 16 to September 8, 1923.

RADIO AND ELECTRICAL EXPOSITION, including amateur home-made set contest, San Francisco, Cal., April 3 to 8, inclusive.

The Dictograd Radio Loud Speaker

THE Dictograph Products Corporation, 220 West 42nd Street, New York City, has placed on the market the new Dictograd radio loud speaker. It is mounted in a mahogany finished hardwood cabinet. An adjusting dial in the front of the cabinet regulates the air gap between the pole shoes and an especially made secret alloy diaphragm. The adjusting mechanism operates through a shaft, pinion and gear. Changing the air gap varies the pull of the magnet upon the diaphragm, thus enabling the loud speaker to be tuned up in complete harmony and resonance with the receiving set.

The Dictograd radio loud speaker is designed to operate on any vacuum tube receiving sets, using two stages of amplification, but good results are often secured on sets employing but one stage of amplification, dependent upon the type of set used and the distance from the broadcasting station. This loud speaker requires no external batteries. In its design and construction is concentrated 20 years leadership in the art of sensitive sound transmission. Dictograph experience in the manufacture of the Acousticon for the deaf, the secret service dictograph, and the Dictograph system of interior telephones, has enabled the production of this perfected radio loud speaker.

Crosley Produces "Radarios"

The Crosley Manufacturing Company, Cincinnati, Ohio, operating radio broadcasting station WLW, calls attention to their original and novel plays which they have christened "radarios." They are a creation of Robert F. Stayman, editor of the Crosley "Radio Weekly." Radarios will continue to be on the weekly programs sent out from the large station at Cincinnati. They were started some time ago and have proven very successful, as the written applause (telegrams and letters) testify.

International Travel Exposition

The second annual International Travel Exposition, will be held at Grand Central Palace, New York City, from April 9 to 14. Although many radio fans do their travelling through the ether, no doubt others will be interested in the exhibits and features of this exposition which have been gathered from the four corners of the earth.

A B C of Aviation

By CAPT. V. W. PAGÉ. This book describes the basic principles of aviation, tells how a balloon or dirigible is made and why it floats in the air. Describes how an airplane flies. It shows in detail the different parts of an airplane, what they are and what they do. Describes all types of airplanes and how they differ in construction; as well as detailing the advantages and disadvantages of different types of aircraft. It includes a complete dictionary of aviation terms and clear drawings of leading airplanes. The reader will find simple instructions for unpacking, setting up and rigging airplanes. A full description of airplane control principles is given and methods of flying are discussed at length.

This book answers every question one can ask about modern aircraft, their construction and operation. 275 pages, 150 specially made illustrations with 7 plates. Price, $2.50

Composers and Publishers Want Radio Users to Pay Fee

Representatives of the American Society of Composers, Authors and Publishers have been in conference with representatives of great broadcasting stations trying to adjust questions of alleged infringement of copyright in connection with radio. It was proposed that the government be requested to collect a license fee from every radio receiving set in the country to compensate music and song writers whose work is used by the broadcasting stations.

E. C. Mills, Chairman of the Executive Board of the Music Publishers' Association, urged that the 588 public broadcasting stations be reduced to 40 and that the selection of programs be controlled by officials representing the public in the vicinity of the station and by others representing the Department of Commerce.

A number of interesting points were taken up in conference between the copyright owners and the radio men. After a statement of the position of the song and music writers, A. H. Griswold, representing the American Telephone and Telegraph Company, asked:

"Is it your position that, having received a royalty on music that is recorded on a phonograph record or player roll, you would expect additional royalties if that roll or record is played again at a broadcasting station?"

"Absolutely," replied Mr. Mills. "I will explain that point. The royalty that we receive under the law from the manufacture of a phonograph record, for the right to mechanically reproduce a copyrighted musical composition, is in consideration of a right to manufacture, not a right to publicly perform; and the right to manufacture does not include the right to publicly perform."

William H. Easton, Vice President of the Westinghouse Electric & Mfg. Company, here interrupted:

"A radio is put in a restaurant. If it has been installed there and is used to play a broadcast program for the diners, is there liability for a third payment?"

"Certainly," replied Mr. Mills. "This would constitute a public performance for profit."

"It seems to me," said Mr. Easton, "that if you were paid once for public performance on that composition, that two payments should not be made for the same rights."

The song writers and composers are accused by the radio men of failing to make allowance for the value rendered by radio in introducing music to the public. The former deny the benefit.

Radio Compass Saves a Sinking Crew

Radio advices received last week by the Cosulich Line, at its New York City offices, stated that twenty-four members of the crew of the sinking Italian freighter "Giulia" had been rescued following three attempts on the part of life boats to reach the vessel. The message from Captain Ettore Zar of the "President Wilson," which made the rescue, stated that he had located the "Giulia" by means of the radio compass. The SOS call was picked up at a distance of 370 miles.

Radio Aids in Reporting Crop Damage

The Bureau of Agricultural Economics Department of Agriculture, has estimated the damage to the peach crop in Georgia, by the recent freeze at 37 per cent. The statistician of the service pays this official tribute to radio in his report: "This is the first crop report on record where material was secured by aid of radio. Acknowl-

(*Continued from page 21*)

Watch Your Heels, Mr. Anthony

From Hugh Taylor, 1434 Meridian Pl., N. W., Washington, D. C.

ON running across Mr. Robert Anthony's claim to the "Radio Golf" record in the Jan. 27th issue of the RADIO WORLD, I decided to send in my record. I have a single-circuit regenerative detector and two stages of audio-frequency. The following are the stations received on March 8, 9, and 10:

March 8, Three Hours' Play—WAC, Schenectady, N. Y., 400 miles; WOR, Newark, N. J., 218; WIP, Philadelphia, Pa., 136; WBZ, Springfield, Mass., 367; WEAF, New York, N. Y., 228; WJZ, Newark, N. J., 218; CFCF, Montreal, Canada, 669; WSB, Atlanta, Ga., 648; WCAD, Canton, N. Y., 200; WDAO, College Park, Ga., 700; WCAE, Pittsburgh, Pa., 302; KSD, St. Louis, Mo., 824; WHAS, Louisville, Ky., 663; KDKA, Pittsburgh, Pa., 302; WNAC, Boston, Mass., 463; WSV, Little Rock, Ark., 1,200 miles. Six local stations. Total, 7,544 miles.

March 9, Three Hours' 30 Minutes' Play—WOR, Newark, N. J., 218 miles; WUZ, Newark, N. J., 218; WEAF, New York, N. Y., 228; WGM, Atlanta, Ga., 648; WGY, Schenectady, N. Y., 400; WGI, Medford Hillside, 400; WBZ, Springfield, Mass., 367; WEAR, Baltimore, Md., 40; CKAC, Montreal, Canada, 669; CPCA, Toronto, Canada, 425; WHAS, Louisville, Ky., 663; WCAE, Pittsburgh, Pa., 302; KSD, St. Louis, Mo., 824; WMC, Memphis, Tenn, 898; KDKA, Pittsburgh, Pa., 302; WGV, New Orleans, La., 1,200. Nine local stations. Total, 7,892 miles.

March 10, Five Hours' 45 Minutes' Play—WJZ, Newark, N. J., 218 miles; WOR, Newark, N. J., 218; WGY, Schenectady, N. Y., 400; WEAF, New York, N. Y., 228; WOC, Davenport, Ia., 1,000; WHAS, Louisville, Ky., 663; WHAB, Galveston, Texas, 1,500; WDAY, Fargo, N. D., 1,525; WCAE, Pittsburgh, Pa., 302; CFCA, Toronto, Canada, 475; WMC, Memphis, Tenn., 989; WNAC, Boston, Mass., 463; WLAG, Minneapolis, Minn., 210; WMB, Auburn, Maine, 675; WLAK, Bellow Falls, Vt., 576; WJAZ, Chicago, Ill., 770; 8XN, Lewisburg, Pa., 225; KDKA, Pittsburgh, Pa., 302; WIP, Philadelphia, Pa., 236; WBZ, Springfield, Mass., 367; WHAM, Rochester, N. Y., 394; WSB, Atlanta, Ga., 648; CFCF, Montreal, Canada, 667; WDAF, Kansas City, Mo., 1,171; KFI, Los Angeles, Cal., 2,980; WGM, Atlanta, Ga., 648; WDAU, College Park, Ga., 700; WDAP, Chicago, Ill., 790; WFI, Philadelphia, Pa., 136; PWX, Havana, Cuba, 1,590; WLAM, Springfield, Ohio, 490; WKY, Oklahoma City, Okla., 1,416; WPAL, Columbus, Ohio, 487. Total, 18,408 miles.

Grand total, 40,628 miles in 12 hours, 15 minutes. Consider my distance and my time. The distance is further, the time shorter. I leave it for the Editor to decide. Mr. Robert Anthony's time was 14 hours and 20 minutes. Distance, 39,348 miles.

* * *

Not Pretentious, But Strictly DX

From F. R. Tilton, Jr., 287 New York Ave., Brooklyn, N. Y.

AM enclosing list of stations I have received with a single-tube regenerative set. The farthest I have received is Fort Worth, Texas, a distance of 1,850 miles:

WDAP, Chicago, Ill.; WBAP, Fort, Worth, Texas; WDAF, Kansas City, Mo.; KDKA, Pittsburgh, Pa.; WHAS, Louisville, Ky.; WAAZ, Emporia, Kan.; WHAZ, Troy, N. Y.; WNAC, Boston, Mass.; WEY, Wichita, Kan.; KSD, St. Louis, Mo.; KYW, Chicago, Ill.; PWX, Havana, Cuba; WOH, Indianapolis, Ind.; WOZ, Richmond, Ind.; WOC, Davenport, Ia.; WWJ, Detroit, Mich.; WWI, Dearborn, Mich.; WSB, Atlanta, Ga.; WBZ, Springfield, Mass.; WGY, Schenectady, N. Y.; WGI, Medford Hillside, Mass.; WFI, Philadelphia, Pa.; WOO, Philadelphia, Pa.; WIP, Philadelphia, Pa.

The majority of the above stations have been received after 10 o'clock at night. Not counting the local stations.

* * *

Another Single Circuit Record

From Marvin Shew, 64 Long Branch Ave., Long Branch, N. J.

AS a constant reader of RADIO WORLD I wish to state my interest in the department, "With the DX Nite Owls." My record is not very impressive, but might be of interest to other readers. The hook-up I am using consists of detector and one-step of audio-amplification. I have heard 35 stations during the two weeks that my set has been in use. Some of them are: CKAC, WOC, PWX, CHXC, CEAC, 2,000 miles; WWJ, WBAP, 1,400 miles; WPO, WSB, CFCA, WHAS, WDAP, KYW, KFL, 2,400 miles; WKAQ, 1,600 miles; WDAF, KDYS, 1,900; besides others. My hook-up is a single circuit with which I have heard 12 different states. The antenna I use is 50 feet long, consisting of one wire, 25 feet above the ground.

RADIO BROADCASTING MAP
FOR the benefit of those interested in Radio and those who are becoming interested, Rand McNally & Company have prepared a publication containing a wealth of information of greatest value. It shows in the most comprehensive way, the location of the broadcasting stations, gives their classification, the call letters, wave lengths, ownership, etc., of each.
Everyone who wishes to get the maximum pleasure and enjoyment from Radio should have a Rand McNally Radio Map of United States. It is complete accurate and up-to-date.
The Rand McNally Radio Map of United States is 28x30 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover.

Wants Phonograph Music Eliminated from All Stations

EDITOR, RADIO WORLD: I have observed a communication from one of your radio fans questioning whether WHN should broadcast after 10:30 p. m. I very seldom receive concerts from this station, but when I do receive I have found the music acceptable. I believe that the great majority of listeners-in prefer this nearby music to that of distant stations, the reception of which is uncertain.

There is no doubt there are a great number of radio fans who have the distance itch—myself included—but we must realize that where there is a station broadcasting acceptable material it is giving amusement to the great majority of listeners. But when we have a station which makes a habit of passing out only phonograph music I think that station should be silenced. I make particular reference to the Paterson station, WBAN. It is common practice among a large number of fans in Paterson to shut off their receiving sets while WBAN is operating. Their modulation is exceedingly poor; and this adds insult to injury, especially after having listened to a first-class concert from WJZ, and then WBAN comes in with its noise and phonograph music. If the station would put out acceptable music, or lectures, or anything of an educational nature, I am sure listening in to distance stations would come second.

There is another small station which broadcasts entertaining material, and that is WRW, of Tarrytown, N. Y. When this station is operating it is generally at a late hour, but it does not interfere with distance work if the fan is so inclined.

There is only one other station I know of that is as bad as WBAN regarding the quality of its broadcasting material, but I have so far been unable to get its call.

I think it would be well for RADIO WORLD to carry on propaganda to have continuous performance of phonograph music eliminated from all stations.

Yours very truly,
10 Rodney St., ARTHUR C. MASON.
Glen Rock, N. J.

Court Asked, "Who Owns the Ether?"

THE first court fight over the freedom of the air in radio will take place at the Livingston County Court House at Pontiac, Ill., at the April term. Edward McWilliams, wealthy President of the State Bank of Dwight, last November was granted a temporary injunction restraining G. Wylie Berman, eighteen, an amateur wireless operator at Dwight, from using his broadcasting station because it is alleged to have interfered with the receiving of radio telephone returns in the McWilliams home on election night. Herbert Hoover, Secretary of Commerce; Mitchell Lewis, machine gun manufacturer of New York, and Hiram Percy Maxim, President of the American Radio Relay League, are expected to attend the hearing.

Staten Island Man Denies He "Jazzed" Paris by Radio

THEY are having a hot discussion in Paris as to whether amateurs there actually received last week a wireless message from a Mr. Webb of Tottenville, Staten Island, as has been asserted. W. S. Webb of Tottenville has denied that he was the author of the radio "jazz" that interrupted the concerts of Paris. He said he had a radio equipment, but that it was not suitable for sending messages. Elmore Ragues, another resident of Tottenville, has the only set there powerful enough to send music to Paris. But Mr. Ragues denied that he had forwarded any "jazz." He said that he had no license to send out music, his sending activity being limited to code.

The French authorities are still searching for the "wild cat" station.

AUTOMOBILE CHARTS

By Victor W. Page, M. S. A. E.

Uniform Size— 24 in. x 38 in.—Price 35c. Each.

Location of Ignition System Troubles Made Easy.
In this chart all parts of a typical double ignition system using battery and magneto current are shown, and suggestions are given for readily finding ignition troubles and eliminating them when found. Includes latest Delco, Connecticut and other systems. (24 x 38.) Price, 35 cents

Lubrication of the Motor Car Chassis.
This chart presents the plan view of a typical six-cylinder chassis of standard design and outlines all important bearing points requiring lubrication, and is a valuable guide to the correct lubrication of any modern car. A practical chart for all interested in motor car maintenance. (24 x 38.) Price, 35 cents

While each of the above three charts is complete, the set covers all maintenance instructions for the entire automobile.

Location of Starting and Lighting System Faults.
The most complete chart yet devised, showing all parts of the modern automobile starting, lighting and ignition systems, giving instructions for systematic location of all faults in wiring, lamps, motor or generator, switches and all other units. Invaluable to motorists, chauffeurs and repairmen. Size 24 x 38 inches. Price, 35 cents

Location of Ford Engine Troubles Made Easy.
An enlarged and revised chart showing clear sectional views depicting all portions of the Ford power plant and auxiliary groups. It outlines clearly all parts of the engine, fuel supply systems, ignition group and cooling system, that are apt to give trouble, detailing all derangements that are liable to make an engine lose power, start hard, or work irregularly. This chart simplifies location of all engine faults, and includes instructions for locating Ford electric starter troubles. Size 25 x 38 inches. Price, 35 cents

Location of Motorcycle Troubles Made Easy.
Price, 35 cents

YOU DX HAMS!
Have you seen the hook-up with complete panel layout in full size and all constructional details in RADIO WORLD No. 43, dated Jan. 20?
This hook-up actually goes out and drags the distance in, and lays it at your table.
All that is necessary is to lay the full-page diagram of the panel on your own panel and drill and mark your holes. Simple, isn't it?
If you haven't this copy, send 15 cents to Radio World, 1493 Broadway, New York, N. Y., and copy will be mailed you. Or start your subscription with that number.

Department of Agriculture Wants a Radio News Editor

THE United States Civil Service Commission announces the following open competitive examination:

The receipt of applications will close May 8. The examination is to fill a vacancy in the office of the Secretary of Agriculture, Washington, D. C., at entrance salaries from $1,800 to $2,100 a year, plus the increase of $20 a month granted by Congress, and vacancies in positions requiring similar qualifications.

The duties of radio news editor require suitable experience in either the agricultural or daily newspaper field. It is necessary that appointees be able to comprehend agricultural and scientific work being conducted by the Department of Agriculture, and to put such matter into popular form so that it easily may be sent out over the radio and understood by the layman.

Competitors will not be required to report for examination at any place but will be rated on a practical test, education and experience, and published newspaper articles prepared by the applicant, to be filed with the application.

Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or the secretary of the board of U. S. civil service examiners at the post office or custom house in any city.

Brothers United by Radio After 42 Years

THE Schenectady radio broadcasting station of the General Electric Company—WGY—was the means of reuniting brothers who had been separated for 42 years. Recently David Hill Voorhees, who lives near Schenectady, N. Y., sought the aid of Chief of Police James W. Rynex, of Schenectady, in locating his brother and sister, from whom he became separated 42 years before, when their parents died and the children were adopted by three different families. At the request of Chief Rynex WGY broadcast a message from Mr. Voorhees, who asked that his brother and sister get in communication with him. The message was put into the air, and the following Sunday Mr. Voorhees had dinner with his brother, Howard Hill, a sign painter, in Gloversville, N. Y. No word has yet been received from the sister.

Western Electric Sets Sales Record

THE Western Electric Company, Inc., which is controlled by the American Telephone & Telegraph Company, reports for the year ended December 31, 1922, a surplus, after all charges, including interest and dividends, of $1,144,936 against $823,997 in 1921. Gross sales were the highest in the company's history, topping the previous high record of 1920 by nearly $5,000,000 and exceeding the 1921 mark by approximately $21,000,000. The gross sales for 1922 were $210,941,004.

S. S. "Leviathan" to Have Biggest Radio Equipment

ECLIPSED only in importance by her powerful machinery and delicate controls the radio installation aboard the "Leviathan," which re-enters the trans-Atlantic service some time in June flying the U. S. Lines flag, will be the most powerful and elaborate steamship radio equipment in the world. The contract to equip the "Leviathan" with a super-power marine radio installation has just been signed with the U. S. Shipping Board by the Radio Corporation of America and work in connection therewith is now in progress. The completion of this work will give to America the distinction of radio supremacy upon the seas.

Once a transporter of American doughboys and now a palatial hotel, the "Leviathan's" radio equipment will enable her pasengers to exchange messages with two continents regardless of her position on the high seas. With equipment six times as powerful as that carried by the average ocean greyhound, uninterrupted communication with points 3000 miles distant is assured. Upon leaving her berth in New York Harbor, the "Leviathan's" radio officers will be able to link the huge vessel with various marine centers in Europe and to communicate with America when leaving European ports.

In addition to telegraph service, a radio telephone installation which will provide voice contact with other vessels and shore stations is also to be installed. While it is not expected that a commercial telephone service will be inaugurated immediately upon the "Leviathan" going into commission it is quite probable that shore stations will in the no distant future be erected to handle wireless telephone traffic from ships in mid-ocean to points inland over the conventional land line system. When such arrangements have been made passengers and officers on vessels at sea may establish contact with those on shore at their homes or offices and speak with them with the same facility and ease that accompanies an ordinary telephone conversation.

Aside from its commercial importance the protection of life at sea is the chief function of marine radio service. That this vital function shall be performed with a degree of reliability exceeded by no other vessel, the installation on the "Leviathan" will permit simultaneous communicaiton by telephone and telegraph. A special emergency set will also be installed. Thus should one or two sets become inoperative due to a mishap, the third or emergency set may be relied upon to summon assistance. Furthermore, two of the life boats are fitted with emergency radio apparatus.

The principal transmitter consists of a high-power vacuum tube outfit which will deliver to main antennae about six times as much power as the apparatus now used on the average steamship. A rapid transfer switch will enable the operator to shift the wavelength of this transmitter in an instant. The second is a duplex telephone outfit which will permit simultaneous telephone and continuous wave telegraph communication. The third or emergency sending equipment is a standard spark set which will normally operate on 600 meters.

The Welsh **PEANUT** Detector Tube
W. T. 501—$2.00

Can be used in any tube set or to convert any crystal set into tube set. Used on 3 dry cells or one 6-V "A" battery.

HOW TO BECOME A SUCCESSFUL ELECTRICIAN—By Prof. T. O'Conor Sloane. An interesting book from cover to cover. Telling in simplest language the surest and easiest way to become a successful electrician. The studies to be followed, methods of work, field of operation and the requirements of the successful electrician are pointed out and fully explained. 202 pages. Illustrated. Nineteenth revised edition. Cloth. Price, $1.50. The Columbia Print, 1493 Broadway, New York City.

WIRING A HOUSE. By Herbert Pratt. Shows a house already built; tells just how to start about wiring it; where to begin; what wire to use; how to run it according to insurance rules; in fact, just the information you need. Directions apply equally to a shop. Sixth edition. COLUMBIA PRINT, 1493 Broadway, N. Y. C. Price, 35 cents.

MODEL MAKING—By Raymond Francis Yates. A new book for the mechanic and model maker. This is the first book of its kind to be published in this country, and all those interested in model engineering should have a copy. The first eight chapters are devoted to such subjects as Silver Soldering, Heat Treatment of Steel, Lathe Work, Pattern Making, Grinding, etc. The remaining twenty-four chapters describe the construction of various models such as rapid fire naval guns, speed boats, model steam engines, turbines, etc. 400 pages. 301 illustrations. Price, $3.00. The Columbia Print, 1493 Broadway, New York City.

STANDARD ELECTRICAL DICTIONARY—By Prof. T. O'Conor Sloane. Just issued an entirely new edition brought up to date and greatly enlarged—as a reference book this work is beyond comparison, as it contains over 700 pages, nearly 500 illustrations, and definitions of about 6,000 distinct words, terms and phrases. The definitions are terse and concise and include every term used in electrical science. 767 pages, 477 illustrations. (See page 18 for fuller description.) Price, $5.00. The Columbia Print, 1493 Broadway, New York City.

RAND-McNALLY RADIO MAP OF UNITED STATES—Is 28 x 30 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover. Price, 35c. The Columbia Print, 1493 Broadway, New York City.

OLD MONEY WANTED—$2.00 to $500.00 EACH paid for hundreds of Old and Odd Coins. Keep all old money. Send 10 cents for New Illustrated Coin Value Book, 4x6. You may have valuable coins. Get posted. We pay CASH. Clarke Coin Company, Ave. 83, Le Roy, N. Y.

BEAUTIFUL WHITE TEETH—YOU can have beautiful white teeth without toothbrush, pastes or powders. No matter how badly discolored your teeth are, this harmless secret will make them white. Economical, sanitary. Price, 25c. AMERICAN SALES CO., Box 1278, San Francisco, Calif.

MANUFACTURERS—Rights on absolutely the best crystal detector yet developed for sale. Seven to eleven sensitive spots always in reserve. Low manufacturing cost. RADIO EXPERT, 77 Walnut St., Norfolk, Va.

FOR SALE—Paragon Regenerative receiver, R.A.10, Detector, and two-step D.A.2. Both $110.00. Crosley two tube set, $25.00. All apparatus new and guaranteed. Write Philip Coblentz, Middletown, Maryland.

BUILDERS AND EXPERIMENTERS. Do you know that the Reflex circuit is one of the most interesting circuits to construct? You can not guess how much fun you are missing if you fail to try out at least one of these circuits. See RADIO WORLD issues of Feb. 24 and March 3. They contain two fine articles by W. S. Thompson, with plenty of new Reflex circuits to experiment with. Don't miss these! 15c. a copy. RADIO WORLD, 1493 Broadway, New York City.

A COURSE IN MECHANICAL DRAWING—By Louis Rouillion. The author has written a most practical book on the subject of Mechanical Drafting. It fully explains the art of Drawing, Lettering and Dimensioning. It is, by far, the most practical book ever published on this subject, for use in day and evening schools, and more especially adapted for the teacher and for self instruction. Fifteenth edition, revised and enlarged. Fully illustrated. Oblong. COLUMBIA PRINT, 1493 Broadway, N. Y. C. Price, $1.00.

DO YOU WANT TO SAVE MONEY in making your set? Send for the Jan. 27 issue of RADIO WORLD, containing a full-page drawing of how to make filament control rheostats, as well as an easily understandable text, which makes the construction easy. 15c a copy, or start your subscription with this issue. RADIO WORLD, 1493 Broadway, New York.

TWENTIETH CENTURY BOOK OF RECIPES, FORMULAS AND PROCESSES—Edited by Gardner D. Hiscox. This book of 800 pages is the most complete book of recipes ever published, giving thousands of recipes for the manufacture of valuable articles for every-day use. Hints, helps, practical ideas and secret processes are revealed within its pages. It covers every branch of the useful arts and tells thousands of ways of making money and is just the book everyone should have at his command. The pages are filled with matters of intense interest and immeasurable practical value to the photographer, the perfumer, the painter, the manufacturer of glues, pastes, cements and mucilages, the physician, the druggist, the electrician, the dentist, the engineer, the foundryman, the machinist, the potter, the tanner, the confectioner, the chiropodist, the manufacturer of chemical novelties and toilet preparations, the dyer, the electroplater, the enameler, the engraver, the glass worker, the gold-beater, the watchmaker, the jeweler, the ink manufacturer, the optician, the farmer, the dairyman, the paper maker, the metal worker, the soap maker and the technologist in general. A book to which you may turn with confidence that you will find what you are looking for. A mine of information up-to-date in every respect. Contains an immense number of formulas that everyone ought to have that are not found in any other work. New edition. 807 octavo pages. Cloth binding. Price, $4.00. The Columbia Print, 1493 Broadway, New York City.

Subscribe direct or through your news dealer. $6.00 a year, $3.00 six months, $1.50 three months. Radio World, 1493 Broadway, N. Y. C.

MARTIAN BIG 4

The wonderful high grade Crystal

Radio Receiving Set

If you want the Best Tone, the Greatest Volume, the Clearest Enunciation, then you want the BIG 4.
YOU CAN'T GO WRONG when you buy the BIG 4.
No Batteries. Cost Nothing to Keep Up. The Outfit Everybody Wants. Nothing to Get Out of Order. Simplicity, Efficiency, Quality.

Popular Price—Four Points of Superiority

1. The Martian Slider for sharp tuning which produces clearness and volume.
2. The Martian Unique Sensitive Detector, which is responsive to the faintest signal.
3. Can be used with 1, 2, 3 or 4 head sets.

The Whole Family Listens In

4. All Brass Nickle Plated. Non-shrinkable Coil.

Anyone can install and operate the Big 4

thus giving the adult or child a simple set to operate.
Nothing to do but connect Aerial and Ground Wire.

JUNIOR

(CRYSTAL SET)

HEADPHONES

Price Complete $5.00

The Junior is made especially for use with crystal receiving sets. When you place a set on your head you will be surprised how much fuller, sweeter and clearer tones it produces than you have ever heard over the radio before.

A Distinctive Feature

The new screw adjustment makes it possible for the user of the Junior Headphones to receive a volume of sound suited to his inclinations. With just the turn of a screw the phones may be adjusted to receive very strong signals comfortably or very weak signals with the greatest efficiency.

The Coil Windings

The coil windings of the Junior (Crystal Set) Headphones are composed of 300 feet of wire to the coil. The wire is uniform in size and winding. These qualities insure accuracy, power, and a long life for the phones.

The Receivers

Junior receiver shells are made of light, drawn-aluminum which will withstand every abuse; the earcaps are of hard rubber and fit the ears comfortably.
The headbands are the Navy type, made for solid comfort.

Junior (Crystal Set) Headphones Mean Radio Enthusiasm

A trial will convince you that Junior (Crystal Set) Headphones are just what we claim. They will add to your pleasure and to your enthusiasm for the radio.
If your dealer does not have Juniors in stock, write or call us. We will give you the name of one who does.

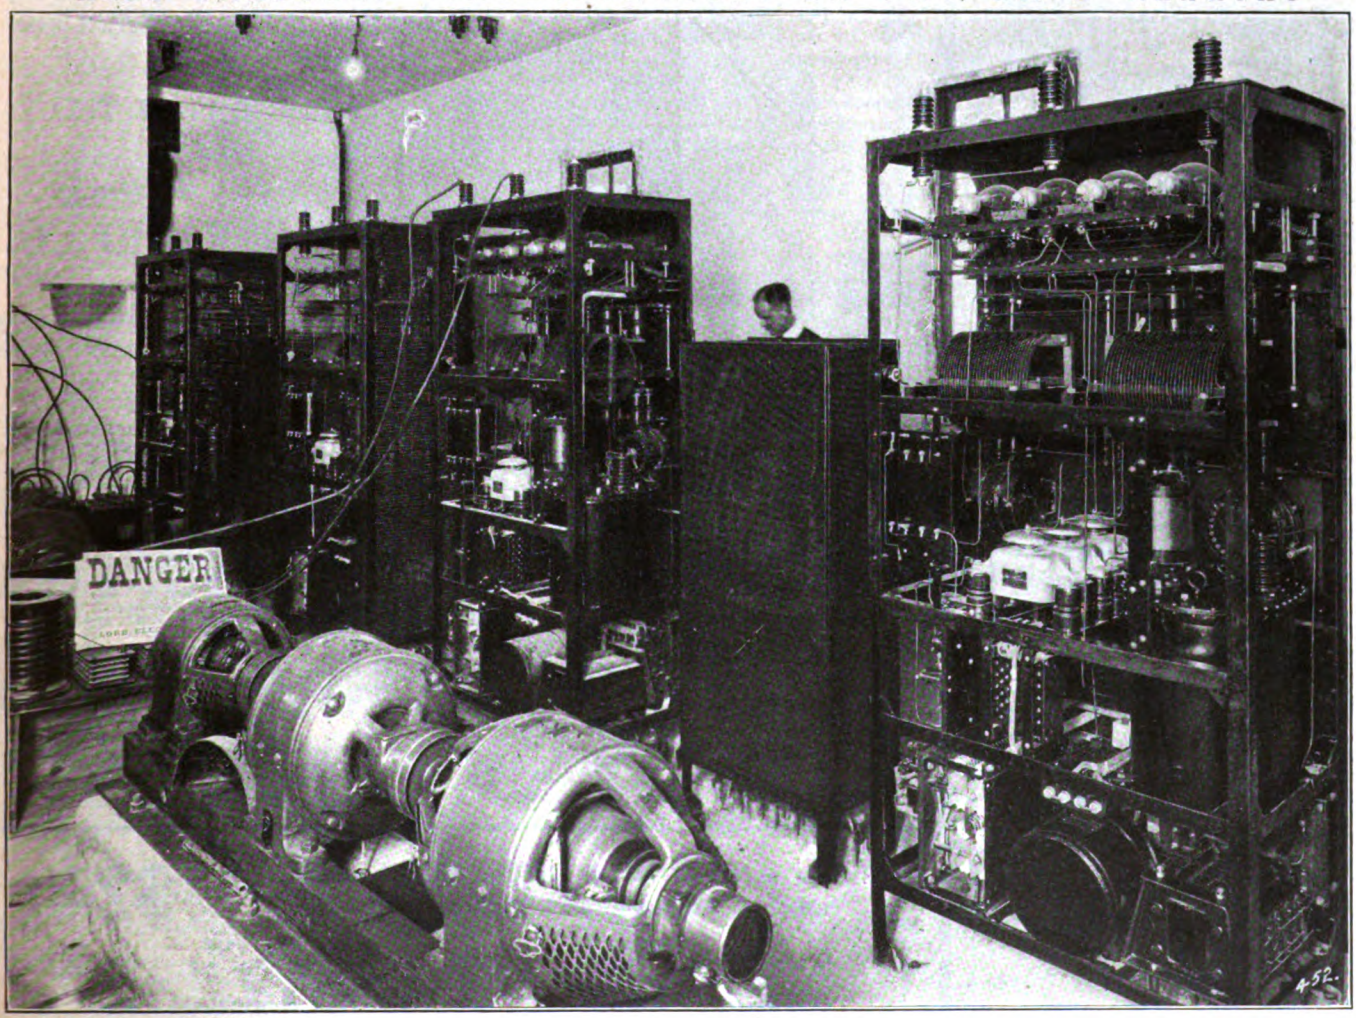
ILLUSTRATED WEEKLY

WILL TRANSMIT SIMULTANEOUSLY ON TWO WAVE LENGTHS



(C. Radio Corporation of America)

The first interior view of the new broadcast station now in process of construction by the Radio Corporation of America atop Aeolian Hall, New York City. This station probably will be in operation early in June and will make possible simultaneous transmission on two wave lengths. The station is owned and will be operated by the Radio Corporation of America. It is the last word in broadcasting development and equipment.

De Forest Radio Control Sold to Detroit Auto Interests

President Charles Gilbert, of the De Forest Radio Telephone & Telegraph Co., Jersey City, N. J., announced on April 6 that a controlling interest in the company had been sold to a group including Edward T. Jewett of the Paige Motor Car Company, Frank W. Blair, President of the Union Trust Company of Detroit; A. C. Allyn, president, and Theodore Luce, vice-president, of A. C. Allyn & Co., bankers, of Chicago and New York, and William H. Priess, inventor of the Priess circuit used in the De Forest reflex set. In a statement Mr. Gilbert said:

"Certain automobile interests who realize the rapid growth and the strong position of the De Forest company through the ownership of the De Forest audion patents, recently became interested in radio as an attractive field for future development, and opened negotiations for the purchase of this controlling interest. As a result there will be a material increase in the cash capital and the resources of the De Forest company, which will enable it greatly to extend its present field of operation. The new company will retain the services of Dr. Lee De Forest for a period of ten years as consulting engineer, with the rights to his radio inventions during that period. The De Forest audion and other basic patents owned by the De Forest company are used by the American Telephone and Telegraph Company, the Radio Corporation, the General Electric Company and the Westinghouse Company. De Forest patents have been used in transcontinental telephony and transoceanic radio."

President Obregon Receives Spanish Concert from United States

President Obregon of Mexico listened in for the first time to a radio concert in Spanish broadcast from Station KSD of the St. Louis "Post Dispatch," in St. Louis, Mo. The President and the "Lady of the Land" were delighted with the results. So much so that they decided to equip Mexican White House with two R. C. Type Westinghouse receivers of American make.

RADIO BROADCASTING MAP

FOR the benefit of those interested in Radio and those who are becoming interested, Rand McNally & Company have prepared a publication containing a wealth of information of greatest value. It shows in the most comprehensive way, the location of the broadcasting stations, gives their classification, the call letters, wave lengths, ownership, etc., of each.

Everyone who wishes to get the maximum pleasure and enjoyment from Radio should have a Rand McNally Radio Map of United States. It is complete, accurate and up-to-date.

The Rand McNally Radio Map of United States is 28x36 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover.

Neat and Efficient Amateur C W Station

By Ray Bright

(C. Photonews, N. Y.) R. L. Koerner's long distance station 2CRQ, New York City

THOSE of you who listen in for DX CW will recognize the call of 2 CRQ, the station of R. L. Koerner, New York City. That is, of course, if you live within 1,500 miles of New York and own anything outside of a crystal set. Well, now that you have heard about the record of this 10-watt station, you are privileged to take a peek at it as well as the owner of the station.

Of course, the most interesting part of the station is the transmitter, which is located directly over the Reinartz receiver on the left of the picture. It is a two tube outfit, with an output of 10 watts. Two 20-watt kenotron rectifiers are used to supply the plate voltage. The Heising system of modulation is employed and the transmitter can be used either for phone, when one tube is used as an oscillator and one as a modulator, or for CW when both tubes are used as oscillators. With special reference to the transmitter, it will be seen that there are three meters used. The one on the extreme left is a milliameter, used in the plate circuit. On the right is a voltmeter to check up on the filament current, while above the transmitter is the thermo-couple radiation meter to allow a check on the current being radiated. As seen in the illustration there are two receiving sets used in the station. The one directly under the transmitter is the well known and widely used Reinartz circuit. By close reference to the picture it can be seen that it is connected to an outside amplifier from which the loud speaker is supplied. The other is a long wave receiver, with two stages of amplification.

It is interesting to note the remarkable strides that have been taken in the design and operation of amateur stations in the past few years. It used to be that in order to even have your station noticed you had to have rotary gaps and OT's sprawled all around the room, threatening to electrocute anybody who didn't sit right in the plum center of his chair. Now, with apparatus such as shown, 1,500 to 3,000 miles is an everyday occurrence. Such a thing as being heard in France and England has lost even its original thrill, and is looked upon as ordinary procedure.

"Build Me!" Cries This New Two-Unit Receiver

By Arthur S. Gordon

A RADIO receiving set which will challenge the interest of all radio amateurs is the one-step amplifier described in the present article. It is so clearly designed that the veriest novice need not hesitate to build it according to plans. The set is extremely handsome, its initial cost is moderate and its upkeep, because of the dry cell tubes used, is negligible.

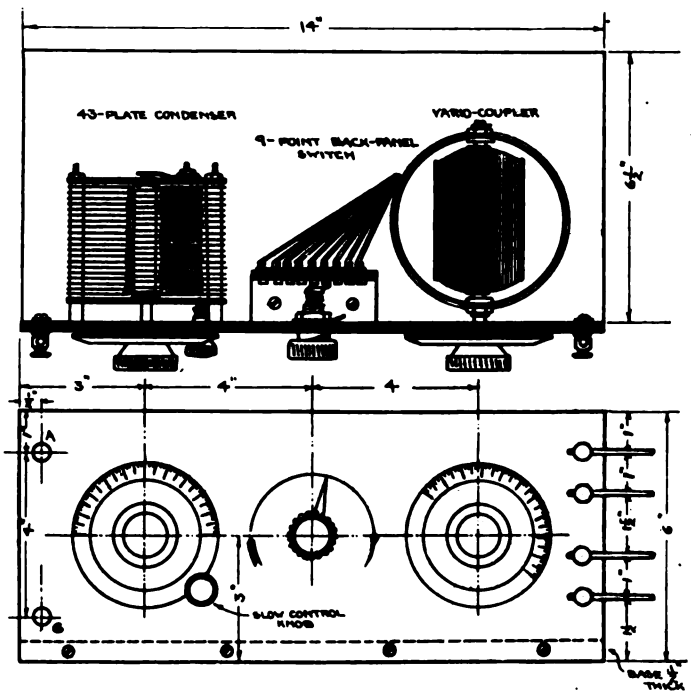

Fig. 1. First section of the two-unit set. This is only the tuning apparatus. The detector and amplification panel are separate.

The coils include all the new broadcasting wave lengths from 200 to 600 meters, with enough inductance to spare for a slight emergency. The receiver is made in two somewhat unusual units which are joined together by four connecting wires to make the arrangement complete. The first unit is called the tuning unit. It consists of a variable condenser, a variocoupler, and a back-panel switch for varying the number of turns on the primary on the variocoupler. The second unit—the electron unit—consists of the tubes, rheostats, telephone jacks, the grid-leak condenser and the audio-frequency transformer.

This is not the usual arrangement, but it has the charm of being distinctive as well as entirely logical. Briefly its advantages are these: The electron unit is perhaps the one that will remain the same as long as the amateur uses dry cell tubes. It is, in a sense, a detached portion of the receiver, having a form of permanency that the other portion does not have. For styles and ideas in tuning devices often change, and it is altogether possible that the amateur may later wish to install another standard type of coupler. It may even be the case that a tuning device of his own design needs trying out. All this will necessitate an almost complete re-building of the tuning unit. In such a case, the electron unit may be disconnected and removed from the scene of replacement, ready at any moment to be reconnected to any combination of tuning devices the amateur decides to install.

The hook-up used is the justly famous single circuit Armstrong regenerative, using the rotor, or movable coil of the variocoupler, as a feed-back inductance. This circuit has been proved and tried in a thousand different ways. It is the basic circuit from which amateurs begin a fascinating career of experimentation. The popularity of this circuit is an adage, and this, combined with its truly remarkable results, make it ideal for the radio beginner. Be neither timid nor alarmed because of the extra tube. One stage of amplification is not only desirable, but inevitable; and this article will explain fully the necessary steps for its complete installation.

The Tuning Unit

The first section of this receiver is called the tuning unit because in it are included only those instruments necessary for bringing in or tuning out a station. It consists of three instruments. They are mounted on a panel from left to right in the order named: Variable condenser, inductance switch and variocoupler. Fig. 1 shows the exceptionally neat arrangement with all the elements drawn to scale. The variable condenser is any standard 43 plate condenser, with or without a vernier attachment. A vernier is an extra device which permits of very fine adjustment and should the prospective builder buy, or already have, a condenser that is not fitted with such a device, it is recommended that a minute control knob be fitted to the dial of the condenser, in order that very slight variations may be secured. Such a knob is shown in place in Fig. 1. It may be bought very cheaply at any radio store.

The inductance switch is a back-panel device with nine switchpoints, each going to a tap in the primary winding of the variocoupler. These switchpoints are mounted in the usual semi-circle on a separate piece of bakelite, which stands 5 inches high and 3 inches in a vertical position one inch to the rear of the panel.

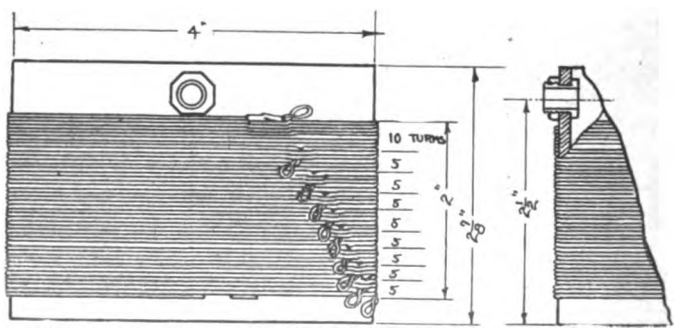

Fig. 2. Detailed sketch of the primary of the coupler, showing the manner in which taps are to be taken. If a fibre tube is used to wind the coil, the brass bushing will be unnecessary.

They are connected with the taps on the coils by straight pieces of bare copper wire or bus bar. The switch is controlled from the face of the panel by a standard switch knob, which is changed over a trifle so that its arm is in the rear instead of in the front of the panel.

The variocoupler is of a favorite type and is selected for use in this set because of its extreme ease of construction. There are other more intricate ways of making variocouplers, and there are other forms of

(Continued on next page)

Digitized by Google

(*Continued from preceding page*)

tuning devices; in fact, so many that the prospective builder is bewildered as to which is the best. Nothing is claimed for this particular tuner that is not claimed for others, excepting that it has been designed to receive on the increased number of wave lengths now released for broadcasting work. The number of turns have been closely figured out so that there is a minimum of dead end effect, which is a detrimental element caused by the proximity of the unused portion of the coil to that portion which is at that moment in tune with the incoming signals. It is extremely selective, as many as six different stations being received with

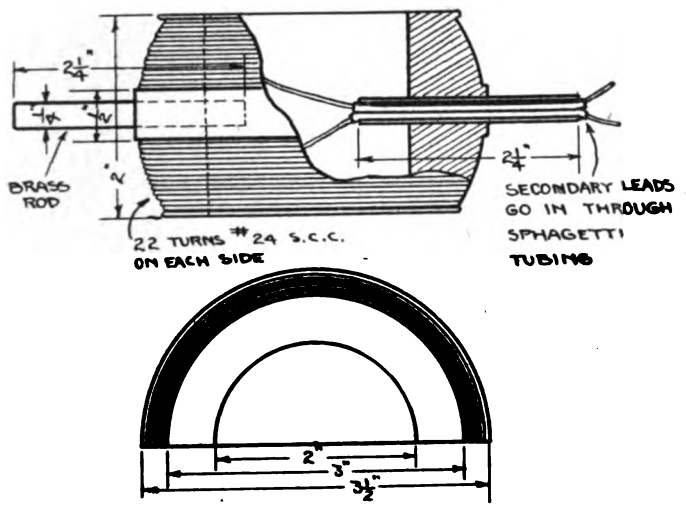

Fig. 3. The rotor of the coupler. The leads are brought out through the hollow tubing, eliminating copper-braided "pigtail" connectors.

one-half turn of the rotor, the condenser remaining untouched at the time.

The two coils of the coupler are the primary and the secondary, the last mentioned being in this case the tickler coil as well. The primary is wound on a 4-inch cardboard or bakelite tube with 50 turns of No. 22 s. c. c. copper wire. There are nine taps taken from the coil, the first being after the initial ten turns, the others in succession every five turns thereafter. The beginning of the coil is also twisted into tap form, and later connected to the aerial binding post. The holes for the shaft on which the secondary revolves, are drilled 2½ inches from the bottom of the winding. They should be large enough, in the case of a cardboard tube, to take some sort of brass or fibre bushing, as

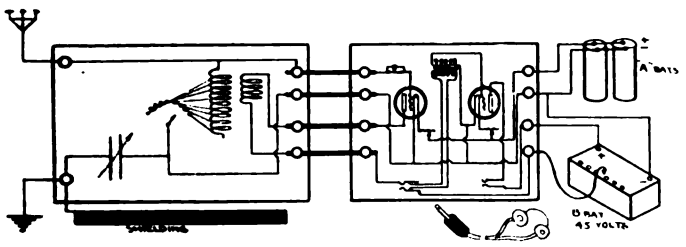

Fig. 4. Schematic diagram illustrating the wiring of the two units. Looks intricate, but is easy when you study it awhile.

shown in the detailed sketch of the primary, Fig. 2. A bakelite tube does not need this bearing surface.

The movable coil is wound either on a ball or on a cardboard tube. Forty-four turns of No. 24 s. c. c. copper wire are required, 22 turns to go on each side of the spindle hole. The spindle, or shaft, on which the rotor turns is of two separate pieces, one of which must be brass or copper tubing. It is through this tubing that the secondary leads come out into the remainder of the circuit. Fig. 3, which is a detailed sketch of the rotor, shows this clearly.

In winding the secondary on a ball, there is an unavoidable break in the wire at the center of the form, where the turns cross over from one side to the other. Starting at any side of the rotor, it is easy enough to wind the 22 turns uphill, but when it comes to crossing over and winding the next 22 turns downhill, the trouble begins. If you cross immediately to the outer edge and begin the second half of the winding as you did the first, you disturb the continuous flow of current through the coil. The only way to do is to start separate windings at each edge, and join the two inside ends at the center of the ball, either inside or outside the form. Be sure that the turns on both sides of the rotor are wound in the same direction.

The assembly of the tuning unit is indicated in Fig. 1. The panel on which the instruments are mounted is 14 inches by 6 inches high. It is of hard rubber or composition board, is lined with tinfoil on its inside face, and is fastened to a wooden base 14 inches long by 6½ inches wide. The tinfoil is to eliminate the disturbing effects of an annoyance known as "body capacity." The foil is cut away at various places so that it does not touch any instrument or part of an instrument. It is cut away from the binding posts and no wires are allowed to touch it. The only connection it has with the remainder of the set is a tinfoil lug which connects the shield with the ground binding post of the panel. Without this connection, the purpose of the shield would be nullified.

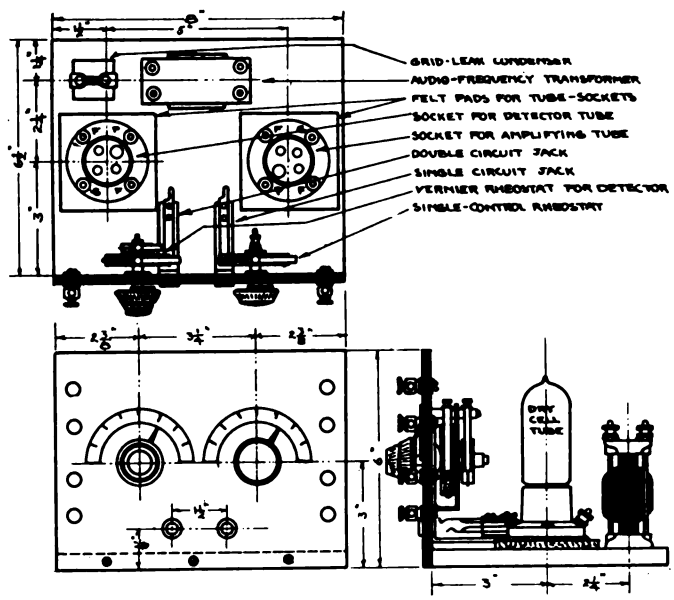

Fig. 5. The detector-amplifier unit, showing arrangement of instruments, as well as dimensions for duplicating the layout.

There are six binding posts on the face of the panel. One each for the aerial and ground on the left edge, and four others on the right edge. These four are the terminals of the tuning unit, and connect with a corresponding four on the left edge of the electron unit. The inside wiring for the tuning unit is shown in Fig. 4, which also continues the hook-up into the second section of this interesting receiver.

The Electron Unit

This unit will appear to the uninitiated to be almost hopelessly intricate. Such is not the case, and after you have read the following explanation and carefully examined Fig. 5, which is an assembly drawing of the electron unit, you will have no difficulty in constructing this particular part of the set. Read slowly and take in every word of the description.

There are two tubes used in this set, both of which

Why Do You Read Radio World?

The number of readers of RADIO WORLD has increased so appreciably during the past few months and there has been such a renewed demand for the paper on the newsstands in New York City and throughout the entire country that the editor is curious to know what particular features of RADIO WORLD appeal to this big army of readers.

Will you drop us a postal and let us know what you like most in RADIO WORLD?

Every publisher must work hand in hand with every reader of his paper in order to know just how and why his publication is making a hit.

Will you let us know why you read RADIO WORLD?

Address The Editor, RADIO WORLD, 1493 Broadway, New York City.

(*Continued from preceding page*)

are dry cell tubes, which do not need a storage battery for their operation. One tube is the detector of radio signals, while the other is the amplifier of those signals. The tubes are exactly alike in mechanical construction, differing only in the use to which they are put. For this use, they are interchangeable. The filament of the detector tube is fed with electricity by means of a vernier rheostat, which permits very gradual increase or decrease of current. A fine adjustment of this nature is necessary for the most efficient operation of the dry cell tube because, when used as a detector, its filament demands are very "fussy." On the other hand, however, a single control rheostat is used in connection with the filament of the amplifying tube, for it has been proved by practice that a close control here is not necessary.

These two rheostats are mounted on the front of the panel so that they occupy the central position. Beneath them are two telephone jacks, the one at the left, underneath the vernier rheostat, being a double-circuit affair, so constructed that when the telephone plug is inserted it automatically cuts out the amplifying tube. The receiver then operates on the detector tube alone. When the telephone plug is withdrawn from the double-circuit device and placed in the other jack, the amplifier gets in the circuit again, and the complete receiver does its utmost.

There are two other instruments left unexplained—the grid-leak condenser and the audio-frequency transformer. The grid-leak condenser, while a small instrument, is a very important part of the set. It is really a combination of two separate instruments, as its name indicates. Both these instruments, the condenser and the grid-leak, are subject to variations according to the particular tube used as a detector, and for this reason, no set value of either capacity or resistance can be given. The proper values can only be hit upon by experimentation. Perhaps a fixed condenser of .00025 mfds. and a variable grid-leak having a range of from one to five megohms, is the best possible combination. An instrument containing these values can be readily purchased.

The audio-frequency transformer is a matter of choice. There are six or seven types on the market which have been designed especially for use with the dry cell tube. These are, of course, the latest design in transformer construction embodying refinements and improvements not found in earlier models. For this reason these especially constructed instruments are recommended. In buying an audio-frequency transformer ask for and get the very best of its kind. It may cost a little more, but the superior results are worth it.

Mounting all these instruments on the panel and baseboard of the electron unit is a simple matter. The arrangement shown in Fig. 5 is not only extremely neat and symmetrical, but is also expertly designed to give the utmost volume without a quiver of distortion. There are no tube and amplifier noises to this set, excepting those caused by excessive regeneration, which are eliminated by turning down the rheostats. Note that the tube sockets are glued to square pieces of felt, which in turn are glued to the baseboard. These pads, about ½-inch thick, take up the shocks due to knocks and bumps and also eliminate the annoying metallic sounds which would otherwise come from the dry cell tube. To aid this elimination, the wires going to the four binding posts of the tube socket are of flexible material.

The back-panel wiring, while honestly intricate, is not beyond the ability of the modestly ambitious amateur. Fig. 4 gives the hook-up as adapted to the construction of the electron unit, showing eight binding posts on the face of the panel, four of which connect the unit to the tuning panel, while the other four are for the two batteries, the "A" and the "B." The "A" battery consists of two No. 6 dry cells connected in parallel as shown so that their combined output does not exceed 1½ volts. The "B" battery is a 45 volt cell with the usual taps for varying the output. The entire "B" battery current is used in the plate circuit of the amplifier, but the amount which goes into the plate circuit of the detector is varied by a flexible wire which comes from the lowest of the four battery binding posts and goes to the taps of the "B" battery as required.

As an aid in tracing the connections the entire hook-up is given in Fig. 6. In this form it is perhaps more familiar to the reader. To make it more so to those who may not know offhand the radio symbols, the names of the various instruments are given along with the conventional signs.

Now for Results!

The particular set described above was made for Mr. Harold Slater, of Fall River, Mass. With a single wire aerial eighty feet long and thirty feet high, he received consistently all stations within the area bounded by a circle drawn through Kansas City, Mo., and Havana,

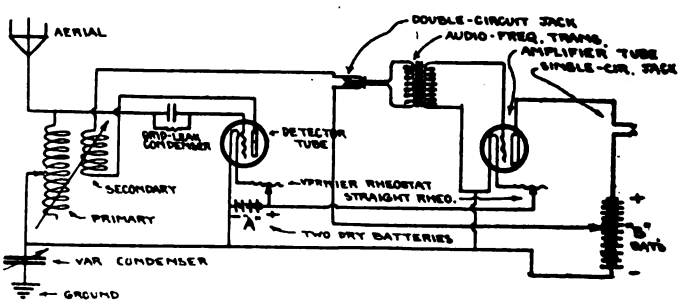

Fig. 6. Hook-up used in the set described in the accompanying article. It is highly selective as well as simple to operate.

Cuba. The range of this set, therefore, is approximately 1,500 miles, enough to reach half-way across the continent from either coast. The volume with which stations not over 500 miles distant were received made it possible to use a horn, a conch-shell, or a small megaphone for loud speaking, attached of course directly to the phones. With such an arrangement music could be heard plainly across a 30-foot room. These results are yours for the trouble—or the fun—of building a duplicate of Mr. Slater's neat and efficient outfit.

"Iowa" is Dead, But Radio Control Secrets Live

THE U. S. S. "Iowa," first radio controlled battleship in the world, went to a gallant death last week in the deep reaches of Panama Bay, sunk by gunfire from her younger but more powerful sister, the U. S. S. "Mississippi." Her flag was not flying—naval guns are never trained on the flag—though she was still an American vessel designated as Coast Battleship No. 4. She was sacrificed in the interests of radio control and naval gunnery.

Her loss amounts to nothing, however, compared with the results of the radio control experiments carried out successfully, and although she carried some valuable and confidential radio control instruments, the radio experts of the navy say no secrets were lost. They had learned all that was possible about controlling the old battleship, so she was turned over to the gunnery and ordnance experts as a mobile target.

Within a short time another ship could be fitted with radio control, and it is understood that many improvements are planned. Rumor has it that one of the laid-up destroyers will probably soon be assigned for radio control experiments and equipped with highly improved apparatus. But which of these fast scouts of the navy will be used has not been decided. Only the allotment of funds and a month or two of time are needed, it is understood. Radio equipment is ready awaiting assembly and installation. By equipping for radio control a high-speed vessel, capable of making at least twenty knots excellent practice could be given the gunners of the navy, it is claimed. The ship would be controlled from a mother craft by radio and maneuvered while under fire.

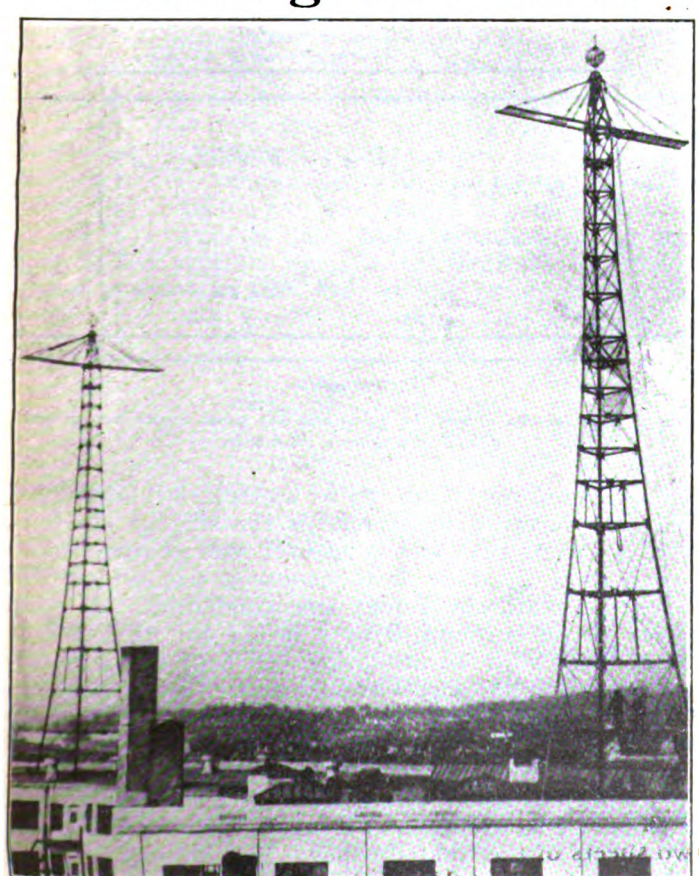
The U. S. S. "CB4," first radio controlled man-of-war, formerly U. S. S. "Iowa," sunk during naval maneuvres in Panama Bay.

Washington Gets RCA Broadcasting Station



(C. International Newsreel)

New Washington, D. C., Broadcasting Towers.

PRACTICALLY the whole continent will be able to hear a new broadcasting call, as yet unassigned, when the RCA station at Washington, D. C., opens up in June. Other than that the station will be of the highest order and latest type, the Radio Corporation refuses to state. Judging from rumors, however, its voice should reach to every corner of the country as well as some of the insular possessions. The new station is located at 14th Street and Park Road known in Washington as Mount Pleasant.

Through the co-operation of the Riggs National Bank and Chas. H. Tompkins, two one-hundred foot fabricated steel towers have been erected on the roofs of the Riggs and Tompkins Buildings in the highest section of Washington where they will serve as new and modern landmarks for the Capital.

The towers have a slight curvature which will give them somewhat the appearance of small Eiffel towers. Their construction is unusual, in that they have three legs instead of the customary four. This reduces wind resistance and makes for stability. A thirty-six foot cross-arm near the top of each tower supports four antenna wires each twelve feet apart. The distance between the towers is 220 feet and the effective radiating length of the antennae 160 feet.

The studio, the reception, transmitting and apparatus rooms are on the second floor of the building. Two motor-generator units will insure an adequate power supply and two tube transmitters will make possible flexible, smooth running programs. It is hoped that the station will be in operation and ready to serve Washington and the surrounding territory within two months.

Telephone Type Condensers of Large Size

By C. White, Consulting Engineer

THE recent development of reflex and other more advanced types of circuits has required the use of rather larger size condensers. Previously the amateur radio fan has been concerned only with condensers up to .006 micro-farads as a very large size. The employment of .25 and .5 condensers was practically unkown for the average use in receiving apparatus until the desirability of confining audio- and radio-frequency currents to certain parts of the circuit and prevent them from wandering where they were of

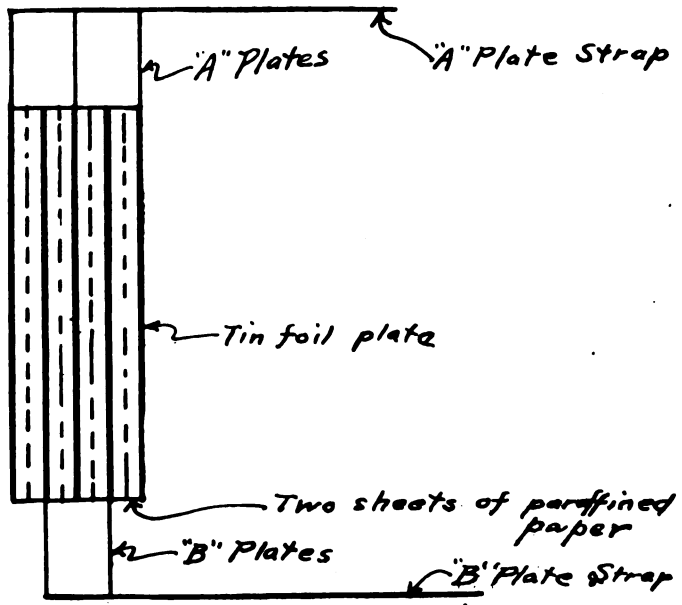

Fig. 1. Diagram showing general method of construction in "piling up" a condenser.

little or no value to the working of the circuit was apparent. In other words, these large condensers are only used as by-pass condensers and not for tuning. Owing to the fact that their employment in amateur radio reception is quite recent it is difficult to obtain them from the ordinary radio dealer; but within a short time I am confident that a .5 mfd. condenser will be as easy to get as a .006. In telephone work, however, the use of relatively large capacities has been constantly practiced since the earliest days of telephone application.

It is an almost common belief that the capacity of a condenser is solely dependent upon the number of plates. This is quite wrong, because the thickness of the insulation and the quality of the insulation are equally as important factors. It is possible to purchase a 43 plate condenser that has less capacity than another 23 plate size. The formula for the design of a condenser is as follows:

$$C = \frac{2.25 \times K \times S \times (N-1)}{10{,}000{,}000 \times D}$$

Where: C is the capacity in microfarads desired.
S the area of one side of a plate.
N the total number of plates.
D the thickness of insulation between two adjacent plates.
K the dielectric constant for the insulation used.

From the above formula it is at once apparent upon which factors the capacity of the parallel plate type of condenser depends. It can be noticed that as we increase S, the plate area, the capacity will be directly increased, and likewise as the number of plates is increased the capacity increases. But as we increase the thickness of the dielectric or insulation D, the capacity becomes less. Then it is quite evident that to obtain a high capacity the thickness of the insulation should be as small as possible, the dielectric constant K should be large, the number of plates should be a maximum, and the area S of one side of a plate must be augmented, until the desired size is obtained. The values of the terms in the equation are in inches and square inches.

Now, for example, let us take the design of a particular size of condenser and run through the complete analysis. Say that it is desired to construct a .25 microfarad condenser. The first thing necessary is to choose the kind of dielectric or insulation to be used, its thickness, the size of the plates, and then from the formula we can easily substitute and determine the number of plates or layers the condenser must have in order to give the wanted capacity. Mica is the ideal substance to use for an insulator, but owing to its high cost it is almost prohibitive. A mica insulated condenser of high capacity, such as 1.0 microfarad, would cost about $15 or more. Hence we must use another substance which is not so good electrically, but less expensive and still capable of serving the purpose. Such a substance is oiled or paraffined paper. This paper can be prepared from a sheet of ordinary heavy tissue paper which is dipped in hot paraffine and allowed to dry. It will be necessary to use two sheets of paraffined tissue paper between two adjacent plates owing to the thinness of one sheet. For plates, thin tinfoil can be used. The

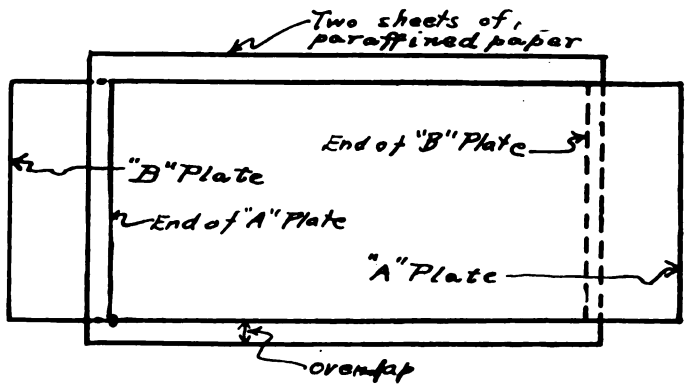

Fig. 2. General idea of how the tinfoil and wax paper should be cut and placed in making a condenser.

dielectric constant, K, for paper so treated is about 2.5. The next factor to determine is the size of plate, S. If S be small then the condenser will require more layers, so it is advisable to choose a size which will make the most convenient size condenser. A good choice would be about 2 by 4 inches for effective or contact area with the insulation. Of course, the actual size of the tinfoil sheets should be two by 4½ inches in order to allow enough tinfoil overhanging to strap the A and B groups together as illustrated in Fig. 1. Now let us substitute in the formula and solve for N, the number of layers or plates. K is 2.5 for paraffined paper; S we have chosen as 8 square inches; and D, for two sheets of the treated paper is .002 inches. Solving for N we find that 111 sheets of tinfoil are necessary.

A Remarkably Simple, Efficient and Flexible Receiving Set

By Robert L. Dougherty

WHEN a man designs a set he tries to accomplish three important things in his construction. The first is efficiency, the second is simplicity, and the third is flexibility. If he can make a set embodying all of these he is perfectly satisfied with himself and also with his results.

A set that embodies all these fine points, as well as quite a few others, was recently built by A. S. Mawhinney, 801 Riverside Drive, New York City. The set itself at first glance would seem to be the conventional three unit honeycomb coil receiver, but upon further inspection, quite a number of novel features assert themselves.

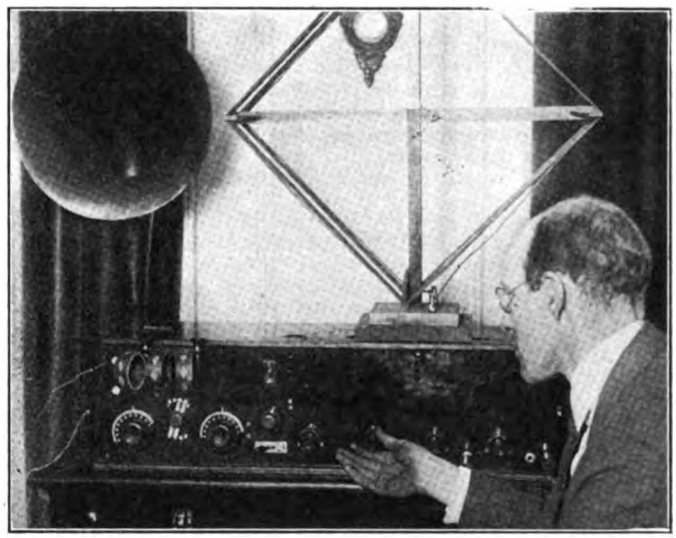
One of the remarkable points of this set is its absolute absence from capacity squeals and howls, and even thought regeneration is used, the coils and condensers can be handled without fear of even detuning distance stations which is an accomplishment in itself.

The set proper when analyzed for flexibility, is really three sets in one, all controlled by means of a single switch. First, it is an extremely efficient three-unit honeycomb regenerative set, which can be used with aerial and ground. With this phase, two steps of audio-frequency can be used. Next, by means of the switch shown in the illustration herewith next to the right hand condenser dial, one can throw on two stages of radio-frequency and use either antenna and ground, with regeneration, or a loop. Then last but not least, it can be used as a triple loop circuit set, by simply removing the honeycomb coils, and plugging in a special loop. The remarkable ease with which any of these circuits are used, and also the remarkable efficiency with which it works, make it a wonderful set.

In the March 24th issue of RADIO WORLD, on page 11, under the heading of "A Fire Escape Antenna" an illustration of the inside of this set was shown. By referring to the picture, it will be seen that five tubes are used. The anti-capacity switch is located directly under the first tube and next to the condenser, and permits either detector and audio-frequency, or radio-frequency, detector and two stages of audio.

Over 112 stations have been copied with this set, using a loop antenna and as is the habit of the builder, phones are taboo, the loud speaker being used exclusively. All long distance reception has been verified by telegram. The furthest reception is Los Angeles, which has been heard clearly on the loud speaker, and a telegram testifies to the fact that the reception was not just a freak, as it has been done numerous times.

Another remarkable feature of the set, and one that is important is the fact that although five tubes are used, there are only 45 volts used on the plates, and although 60 to 100 can be used, it functions efficiently on 45. The Los Angeles reception was accomplished on that plate voltage. In combining radio-frequency with regeneration, it is remarkably quiet, and there is a brilliance to the signals that is startling. The reception is entirely free from tube noises, such as crackling, squealing and howls, which is due to the method of hooking up the transformers, and also the method of mounting them on the sub-panel.



(C. Kadel and Herbert)

A. S. Mawhinney operating the set on which he heard Los Angeles, Cal., from New York City.

When a man can construct a set that is flexibility itself, free from all capacity howls, (you can't make this set howl except by turning the filaments up too bright), and is as efficient as this one is, he truly can say that he has accomplished his aim.

(Continued from preceding page)

But, for average use, it would be close enough to build the condenser by placing on layers until the whole condenser has reached a certain thickness. With thin tinfoil about .0005 inches in thickness, the whole condenser would have to be built up until about ¼-inch thick.

The actual construction data is as follows: Cut 2¼ by 4¼-inch strips from a sheet of the prepared paper, and cut 2 by 4½ strips of tinfoil. Start laying the condenser as shown in Fig. 2, taking especial care throughout the construction to see that in no place do the A and B groups of plates touch each other. The paper should be allowed to overlap the two sides of the plates that are not used for the connecting straps so as to prevent short circuiting two adjacent plates or sheets of tinfoil. Start with a sheet of tinfoil, then two sheets of paper, then another sheet of foil of the B group—that is, with the end hanging over on the other side. About every third tinfoil sheet it is advisable to roll or press the excess paraffine out of the paper by means of a rolling pin or similar object. After the desired thickness has been reached, the condenser can be made rigid by placing two sheets of heavy cardboard on end side and tying the same tight, thus keeping the condenser pressed together. After the plates are strapped together, thus forming the A and B groups, the whole condenser can be placed in a paper or wooden box which can be filled with paraffine to keep moisture out.

If it is desired to construct a condenser four times larger than the one just described it is only necessary to lay plates and paper until four times the thickness has been attained. If it is desired to make one only one-tenth as large the thickness should only be about one-tenth the size of the .25 mfd., condenser. Other sizes can be made in similar proportions.

Second Radio Conference Recommendations Accepted by Secretary Hoover

SECRETARY HERBERT HOOVER, of the Department of Commerce, last week issued the following official statement which is of great importance to all radio users and enthusiasts:

The recommendations by the Radio Conference represent a step in ideal development of measures for the prevention of interference in public broadcasting.

The report recommends making available all wave lengths from 222 to 545 meters for public broadcasting, the various possible bands to be assigned to different stations so as not only to reduce direct interference but also to build up zonal regions of distribution.

The department fully accepts the recommendations of the conference, but there are a number of difficulties in placing the plan abruptly into action: First, the hardship that it may cause to various stations to move arbitrarily to new wave lengths; second, the difficulties introduced by the ship-to-shore communication which are now working to some extent on 300 meters and also on 450 meters.

The conference recommended that the ultimate development for ship communication be to assign for the general purpose of shipping the whole wave area from 600 to 800 meters, different bands being allotted within this area for different shipping purposes. The distress signals from ships now work on 600 meters and the radio compass works on 800 meters. The ship-to-shore communications on 300 and 450 meters are altogether commercial traffic and would be more advantageously carried on with less interruption than today if these services were given the entire field around 700 meters.

In order to make progress in this direction of developing the area from 600 to 800 for ship communication, it is proposed that all ships and all shore stations used for ship communications shall cease using 450 meters between the hours of 7 and 11 p. m., but may use 700 meters at this or any other time. The 300 meters wave length now assigned under the International Convention is very little used and will be used for inland broadcasting, and it is not expected that the ships will avail themselves of the International Agreement in this particular, as it has not proved of practical advantage except to a limited extent.

For internal broadcasting the department proposes to cooperate with the various stations with a view to developing a systematic assignment of wave lengths to the various stations within the broad confines of the recommendations of the conference. In order to carry this out without hardship the following classification of stations will be made:

Class A stations—that is, stations equipped to use power not exceeding 500 watts. In this class it is proposed that the radio inspectors, in cooperation with the station owners, shall assign distinctive wave lengths to each station so far as is possible in the area from 222 to 300 meters. No station will be required to change from 360 unless it so desires.

Class B stations—that is, stations equipped to use from 500 to 1000 watts. In this class it is proposed to similarly offer to license these stations on special wave lengths from 300 to 345 and from 375 to 545 meters, having regard to the maintenance of some ship work on 450 meters as outlined above and again no station will be required to change from 360 unless it so desires.

Class C stations—comprising all stations now licensed for 360 meters. In this class no new licenses will be issued for stations on 360 meters until the plan is entirely realized. Stations which do not wish to move under the general plan may remain at 360 meters, but they will necessarily be subject to some interference at best. It is thought that by the above plan the stations can be gradually brought into accord without hardships.

Under the plan amateurs are given the whole area from 150 to 220, instead of being fixed upon 200 with special licenses at 375. The special licenses hitherto issued for amateurs at 375 will now be issued at 220. Certain special cases will be taken care of otherwise. It is proposed, in cooperation with the amateur associations, to develop an assignment of wave bands in classifications so as to somewhat relieve the present interference among amateurs. It will be remembered that the number of wave bands which can be used among the short wave area assigned to the amateurs is greater in proportion than among the longer wave lengths, and these arrangements expand in the area hitherto assigned to amateurs.

Seven New Broadcasting Stations Licensed

Seven new broadcasting stations were licensed on 360 meters during the week ending March 31. They are as follows:

Call	Station	
KFGL	Arlington Garage, Arlington, Oregon	5 watts
KFIF	Benson Tech. Student Body, Portland, Oregon	200 watts
WWAJ	Columbus Radio Club, Columbus, Ohio	10 watts
WRAK	Economy Light Co., Escanaba, Mich.	200 watts
KFFR	Kirk, Jim, Sparks, Nevada	10 watts
WRAS	Radio Supply Co., McLeansboro, Ill.	20 watts
WSAP	Seventh Day Adventist Church, New York City	250 watts

The following 29 broadcasting stations were deleted during March:

Call	Station
KHD	Aldrich Marble & Granite Co., The C. F., Colorado Springs, Col.
WEAW	Arrow Radio Laboratories, Anderson, Ind.
KFGG	Astoria Budget, Astoria, Ore.
WMB	Auburn Electrical Co., Auburn, Me.
KFCC	Auto Supply Co., Wallace, Idaho.
WEAC	Baines Electric Service Co., Terre Haute, Ind.
KXS	Braun Corporation, The, Los Angeles, Cal.
WCAP	Central Radio Service, Decatur, Ill.
KDYV	Cope & Cornwell Co., Salt Lake City, Utah.
KNX	Electric Lighting Supply Co., Los Angeles, Cal.
KFBV	Ford, Clarence O., Colorado Springs, Col.
KDZM	Hollingworth, E. A., Centralia, Wash.
KON	Holzwasser, Inc., San Diego, Cal.
KQP	Hood River News Co., Hood River, Ore.
KLP	Kennedy, Colin B. Co., Inc., Los Altos, Cal.
WAH	Midland Refining Co., El Dorado, Kan.
WDAH	Mine & Smelter Supply Co., El Paso, Tex.
WLAM	Morrow Radio Co., Springfield, Ohio.
WRAJ	Pickering Co., M. H., Pittsburgh, Pa.
WOAQ	Portsmouth Radio Ass'n, Portsmouth, Va.
WBAB	Potter, Andrew J., Syracuse, N. Y.
KDZQ	Pyle, William D., Denver, Colo.
WGAB	QRV Radio Co., Houston, Tex.
KFAS	Reno Motor Supply Co., Reno, Nev.
KDZL	Rocky Mountain Radio Corp., Ogden, Utah.
WFAS	United Radio Corp., Fort Wayne, Ind.
WFAD	Watson, Weldon Motor Supply Co., Salina, Kan.
KOG	Western Radio Electric Co., Los Angeles, Cal.
WOAY	Wilder, John, Birmingham, Ala.

Broadcasting Continues Popular

DURING the month of March broadcasters increased to 609, but 29 withdrew and their licenses were cancelled leaving, with 21 new stations licensed, a total of 580 operating stations. Of these, thirty are Class B stations on 400 meters and the balance on 360 meters. There they will remain until applications for transfer to the two new classes are received and they are "sorted" out and assigned new waves by the Department.

Resolutions Adopted by the Second National Radio Conference

AT the conclusion of the Second National Radio Conference, recently called to meet in Washington, D. C., by Secretary Hoover, of the Department of Commerce, the following resolutions were adopted and have just been promulgated by the Department of Commerce:

That this conference, and the Department of Commerce subsequently, follow the practice of expressing wave frequency in kilocycles per second, with wave length in meters in parentheses thereafter.

That in assigning a wave band of 10,000 cycles to each Class A broadcasting station they be distributed over five zones throughout the country such that no stations in adjacent zones are closer together in frequency than 20 kilocycles, and that within each zone there be ten stations separated by 50 kilocycles.

That only one wave frequency be assigned to a Class A broadcasting station, which should transmit exclusively on the wave frequency designated and reserved exclusively for that station.

That every broadcasting station should be equipped with apparatus as a tuned circuit coupled to the antenna and containing an indicating instrument or the equivalent for the purpose of maintaining the operating wave frequency within 2 kilocycles of the assigned wave frequency.

That the Department of Commerce establish qualifications for Class A broadcasting stations, including a general minimum and locally suitable maximum power and a quality of program that will warrant assignment of a territorial wave frequency to each particular station, and that the qualifications be similar to those required of the present Class B broadcasting stations.

That the Department of Commerce in its discretion assign Class B broadcasting station licenses in which wave frequencies shall be specified and in which the power ratio between the Class A and B stations shall be at least 2 in so far as is practical for a given locality.

That in granting licenses it is recommended that the Department of Commerce limit the use of power where undue interference would otherwise be caused.

That reading of telegrams or letters by broadcasting stations be not construed as point to point communication so long as the signer is not addressed in person and so long as the text matter is of general interest.

That simultaneous re-broadcasting shall be permitted only on a broadcasting wave frequency, and with the authorization of the original broadcaster and the Department of Commerce.

That the Department of Commerce be requested to insist upon the suppression of harmonic and other parasitic radiation from all radio stations, as for example, by requiring the installation, if necessary, of coupled circuit transmitters at the earliest feasible date.

That spark transmitting apparatus be replaced as rapidly as practicable by apparatus which will produce a minimum of interference.

That the amateur organizations of the United States study the time requirements of the broadcasting of religious services on Sunday and by mutual arrangement with the broadcasters determine upon silent periods which will make possible the reception of such religious services in any given locality.

That when the government conducts services similar to commercial services for which waves or wave bands have been assigned, the government stations shall use the said waves or wave bands.

That the Government have the exclusive use of a band one kilocycle wide centered at each of the following frequencies, 92, 83, 81, 78, and 76 kilocycles, so far as is consistent with public service generally.

That where a line-radio installation produces interference with the reception of signals from beyond the state such line-radio station shall require a license from the Department of Commerce.

That the subject of interference caused by devices not used for radio communication purposes and which are not subject to the present radio law be referred to the projected Sectional Committee of the American Engineering Standards Committee and that in the meantime the members of the conference offer to the Department of Commerce their cooperation in the solution of such immediate problems as may be of a character in which their aid could be of value.

That, in the judgment of the Second National Radio Conference, the prevention of "wilful or malicious interference," as provided for by Section 5 of the Act of August 13, 1912, and the minimization of interference, as provided for by Article 8 of the International Convention, require that the Department of Commerce shall, in its discretion, withhold or rescind station licenses to transmit on specified wave frequencies, at certain times, and on definite powers, and with certain types of transmitters and when, in the judgment of the Department of Commerce such interference would result or does result; and that it is the clear and manifest intent of Section 1 through 4, and Regulations 10, 12 and 18 of Section 4 of the said Act to give the Department of Commerce such authority to withhold or rescind licenses where such interference will result or does result; and that the Second National Radio Conference believes that a decision by the Courts validating the above views will be greatly in the public interest; and that the Second National Radio Conference expresses its willingness to advise and assist the Department of Commerce in the support of the above resolutions in the event of litigation.

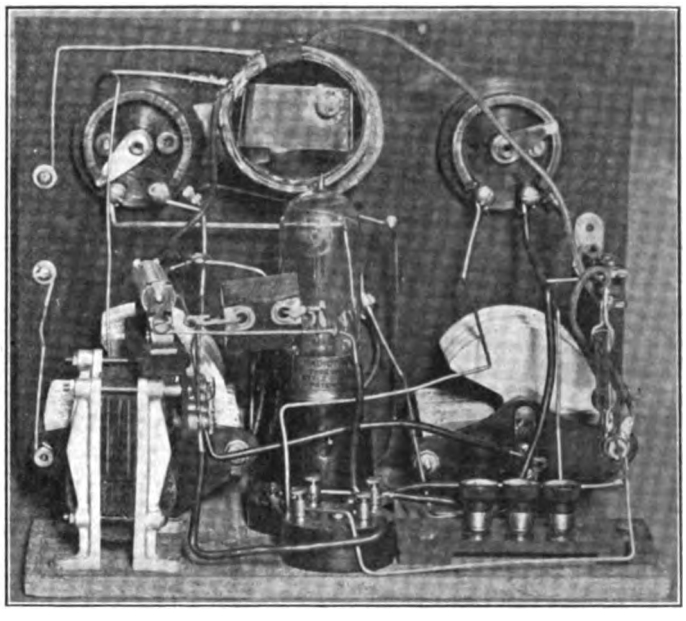
That a copy of the foregoing motion be sent to each concern, organization or association engaged in manufacture of radio equipment, or broadcasting by radio or otherwise interested in radio communication with a request for an expression of approval or disapproval of the motion and an agreement to abide by its provisions.

That the Second National Radio Conference desires to emphasize the limited facilities available for radio broadcasting, and the uneconomic and tentative basis of present-day broadcasting, and that the Conference urges the consolidation in each locality of those desiring the establishment or maintenance of broadcasting and those interested in broadcasting in that locality; to the end that broadcasting conducted in each neighborhood by such a local association will receive public support and be handled in an economic and permanent fashion.

That the great expansion of radio communication has not been accompanied by a proportional increase in the radio personnel and facilities at the disposal of the Bureaus of Navigation and Standards of the Department of Commerce, and that the resulting strain on the inspection and technical forces of the Department of Commerce has been excessive, and has even forced the omission of important activities and investigations, and that the Second National Radio Conference strongly recommends that additional appropriations be granted to the Department of Commerce for its radio inspection personnel and equipment and for its research personnel and facilities. That a committee of three be appointed to wait upon the Secretary of Commerce to present the urgency of this need and the importance of the early provision of funds for these bureaus.

That the present conditions of radio interference with non-local reception and the resulting public dissatisfaction urgently require that the recommendations of the conference be accepted by the Secretary of Commerce and put into early operation by the Department of Commerce.

Lionel Bigman's One Tube Set



(C. Kadel & Herbert)

This one-tube reflex set, built by Lionel Bigman, of New York City, is inexpensive and well worth constructing. It uses a fixed crystal for detector and one tube with reflex action on the plate circuit. For DX reception this set is especially good and remarkable results have been obtained. Local stations have been heard 50 feet from the phones on the loop.

The Functions of the Grid Condenser

By W. S. Thompson, E.E.

GRID condensers can be purchased for such a small sum that many radio enthusiasts neglect this most important part of their receiving set. It is the purpose of this article to discuss the functioning of this piece of apparatus and to clear up some misunderstandings prevalent concerning its use.

As most radio fans are familiar with the theory of a triode vacuum tube, the author will assume that all

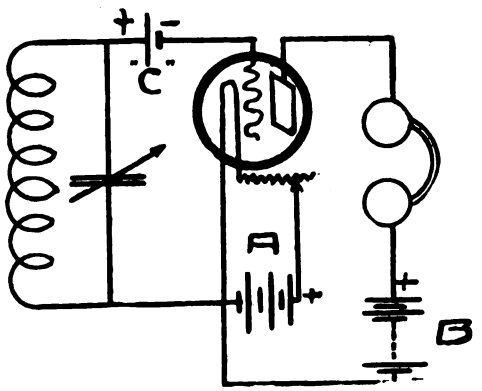

Fig. 1. Fundamental circuit for connecting triode vacuum tube as a detector without using a grid condenser.

his readers understand how a change of potential on the grid controls a flow of current in the plate circuit. Before the grid condenser was first applied to a radio receiving set, the vacuum tube was used as a detector in an entirely different manner than is customary today. The lead from the secondary of the coupling transformer was taken directly to the grid as shown in Fig. 1, using a "C" battery to keep the normal potential of the grid negative with respect to the filament. In order to explain how this arrangement detected and rectified signals, it will be assumed that the signals consist of a series of wave trains as shown in Fig. 2. As this series of wave trains might represent a modulated sustained wave, the discussion will apply equally well for code or phone transmission. Fig. 3 consists of a plate current-grid potential characteristic curve of a modern receiving tube plotted in the conventional manner. The vertical line, E′, represents the normal grid potential as fixed by the C battery in the grid circuit. The horizontal line I′ represents the current flow

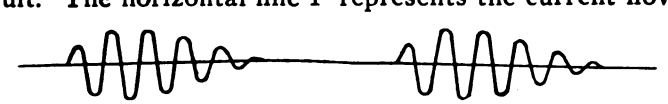

Fig. 2. Conventional method for representing a series of wave-trains sent by a transmitting station.

in the plate circuit when there are no signals being received. An incoming wave train has been plotted on the line E′ and the effect of this incoming wave on the plate current has been plotted on the line I′. A careful examination of the curvature of the characteristic curve will show that when the grid is made positive by a positive half-cycle of the incoming wave, the effect upon the plate current is to increase it more than it is decreased by the grid being made negative by a negative half-cycle. The result of this is that the average value of the fluctuations of the plate current is increased above normal as shown by the dotted line. This increase of the average value of the plate current causes the diaphragm in the telephone to move, and hence causes a sound. The frequency of this sound wave depends upon the number of wave trains received per second. It can be seen, therefore, that due to the sharp knee of the characteristic curve at the operating point the very high frequency radio waves are converted into an audio-frequency sound in the telephones. The normal potential of the grid with respect to the filament is kept negative in this case in order to keep the operating point on the lower knee of the characteristic curve.

When a grid condenser with a grid leak is inserted in the grid circuit, an entirely different action takes place, although it accomplishes the same result. Fig. 4

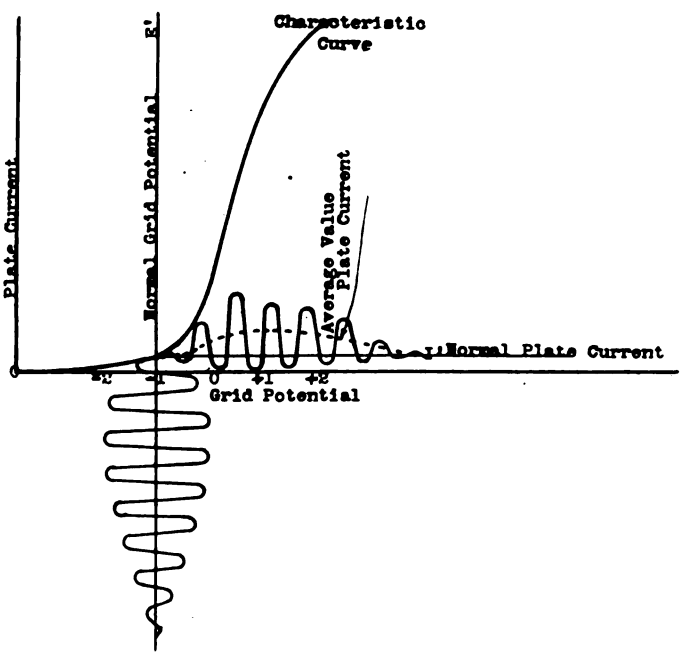

Fig. 3. Plate current-grid potential characteristic curve of triode tube showing rectification of an incoming wave-train.

gives the fundamental hook-up, using a grid condenser in conjunction with the tube to detect signals which will again be assumed to consist of a series of wave trains in order to simplify the discussion. It should be noted that the grid circuit is connected to the positive terminal of the A battery and that there is no C battery used to maintain the potential of the grid at any value. Fig. 5 consists of the grid current-grid potential characteristic curve of a receiving tube, because it is upon the shape of this curve that the detecting action depends. The normal potential of the grid depends upon the value of the grid leak and the RI drop in the filament, so that they should be of such a value that

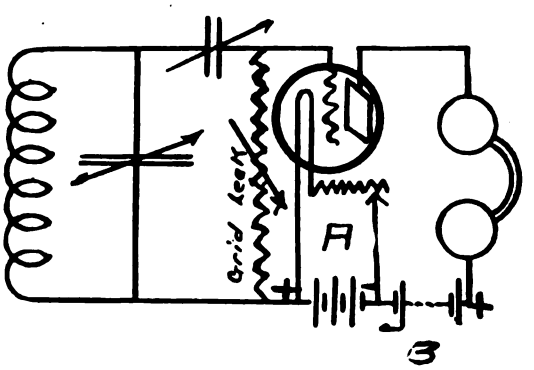

Fig. 4. Fundamental circuit for connecting triode vacuum tube as a detector using a grid condenser with leak.

Just to be in Fashion

If each page of this week's issue of RADIO WORLD were to be placed end to end the edition would reach from Times Square, New York City, to the Post-Dispatch Building, St. Louis, Mo.

The amount of ink used on this week's issue of RADIO WORLD, represented by the same amount of black paint, would be sufficient to paint the New York City Hall and the Aquarium, San Francisco, Cal.

If each revolution of the three presses that were required to print this week's issue of RADIO WORLD were reduced to running footage it would cover the distance between New York City and Portland, Ore.

We do not guarantee that these figures are correct, but as it is the fashion these days for publishers to make such comparisons, we offer them as interesting if not particularly precise.

(*Continued from preceding page*)

the operating point on the curve will be at P. This point P being on the sharp knee of this curve, it will be seen that a positive half-cycle of the wave train will cause a larger increase of grid current than a negative half-cycle will cause a decrease of grid current. This action will cause an accumulation of negative electrons on the grid side of the grid condenser and this accumulation of negative charges will make the potential of the grid negative and hence cause a decrease of plate current. When a wave train has passed and been rectified, the negative charge will leak from the grid condenser through the grid leak and the potential of the grid will again become normal. Thus it can be seen from Fig. 6 that each wave causes a decrease of plate current, the frequency of which depends upon the number of wave trains received per second.

Comparing the two methods, the reader will note that with no grid condenser, the detector action depends upon the operating point on the plate current-grid potential curve and that each wave train causes an increase of plate current, while the detector action using a grid condenser with a grid leak depends upon the operating point on the grid current-grid potential curve, and that each wave train causes a decrease of plate current. The majority of modern receiving sets use the grid condenser method because it is more sensitive, using the receiving tubes which are available to the average amateur. However, some of the oxide-coated filament tubes would be better detectors using the no grid condenser method.

In designing the grid condenser and grid leaks, there

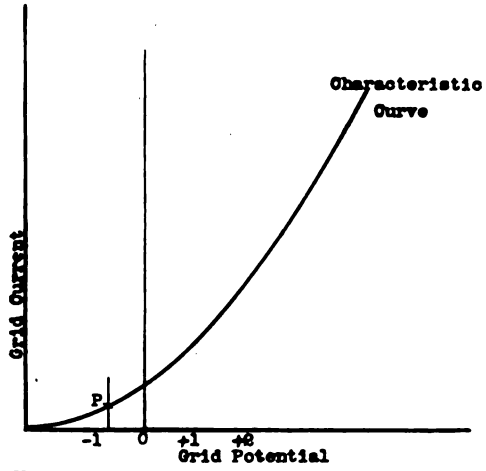

Fig. 5. Grid current-grid potential characteristic curve of a triode vacuum tube showing operating point on knee of the curve.

are several very important factors which must be considered and a great many more which affect the operation of the tube in one way or another but are not important enough to materially decrease its efficiency. The grid condenser must be designed to conform to two limits; that is, it must be small enough so that the accumulation of negative charge will materially affect the potential of the grid and also it must be small enough so that the accumulated charge will leak off during the time between wave trains. The other limiting factor is that the condenser must be large enough so that it will not rob the grid of signal voltage. If the capacity of the grid condenser was too small the signal voltage across the grid-filament would be very small due to the fact that when two condensers are in series with a source of electromotive-force the voltage across each is inversely proportional to the capacity of each. In other words, the smaller of the condensers will have the largest voltage drop so the grid condenser should be large enough to give most of the signal voltage to the grid-filament capacity in order to get the largest change of potential on the grid. The values of grid condensers used today are therefore the largest values that will operate efficiently with a given tube.

The value of the grid leak depends upon the value of the condenser used and should be of such a value

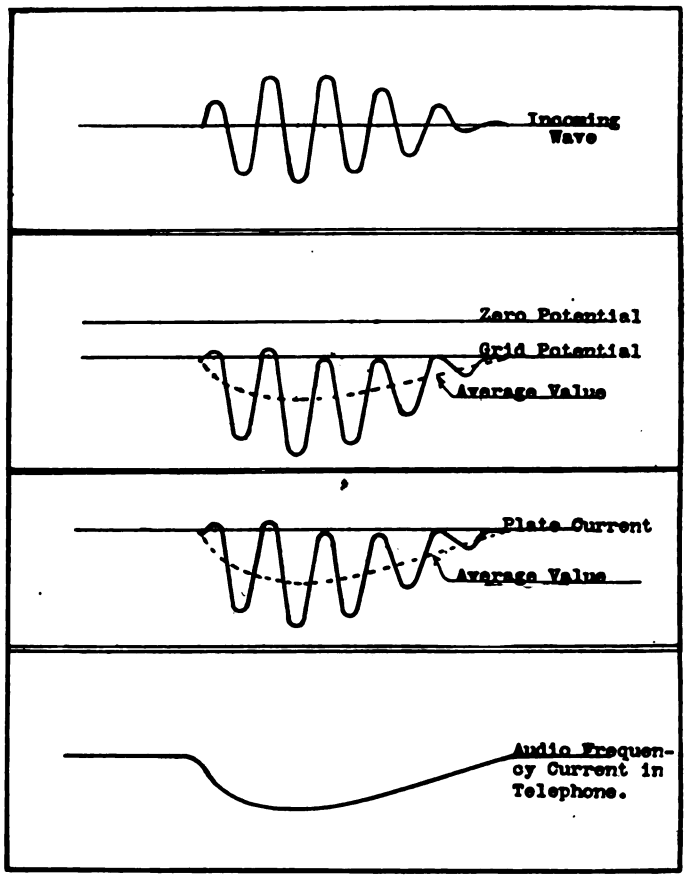

Fig. 6. Showing the effect of an incoming wave on the grid potential and the plate current when a grid condenser is connected in series with the grid.

that the accumulated charge will leak off between each successive wave train without making it so small in resistance that the charge will not accumulate in the condenser.

The only method for obtaining the correct values for the grid condenser and the grid leak without going very deeply into mathematical equations is to experiment with a given tube until best results are obtained.

Radio and the Woman

By Crystal D. Tector

A YOUNG financier who lives right around the corner from me decided that he wanted a set, but not having money enough to get one conferred with some of his fellow "money masters" and they floated a stock issue to the amount of $25.00. The stock was ten cents per share, and he will have 249 partners in his venture. Of course, the young man will have to be repaid for all his trouble, so the set will be installed in his house, and his partners will have to come over to listen in. Well, J. Pierpont Morgan had to have a start and radio evidently gave this young man an idea in high finance that will benefit him in later life. Just imagine if, 60 years from now, he can look around his spacious office in some downtown bank building and say: "Well, radio certainly gave me this!"

* * *

'Member last week, girls, I threatened to publish my DX letter if I received any encouragement? Well, here I am, and I am proud of it because it was all on one 216A tube, using my Flewelling and a hundred foot antenna without ground: KSD, St. Louis, so loud that I thought it was Ridgewood; WBAP, Fort Worth, Texas; WGM, Atlanta, Ga.; WSB, Atlanta, Ga.; WDAP Chicago, Ill.; WGY, Schenectady N. Y.; KFEP, Denver, Colo.; WMZ, Memphis, Tenn.; WDAF, Kansas City, Mo.; WIP, Philadelphia; PWX, Havana, Cuba, and of course WEAF, WJZ, WHN, WAAM and a score of other nearby stations. Now if some of the girls don't send in some of their DX records, I shall be sadly disappointed as I at least want to publish one letter a week. The editor says that one letter a week is all I can publish, so you had better address me early in the week if you want to get into my column.

* * *

Now that the nice, balmy spring days are coming, F. H. is very loathe to stay in the house, and at the same time he doesn't want to have the loud talker out on the porch. So he ran a couple of wires from the set outside to the rail, and put a couple of weatherproof jacks under the rail. Now he can sit outside in comfort with a pair of phones over his ears and listen to all the concert, and I 'spect he gets thirty winks between programs. He said that the only drawback is that he can't tune it, and has to listen to what I pick out for him. Well, I will use some of that good judgment, and imitate the operator in the Ritz Apartments over in Newark, N. J., and then see if I can't keep him satisfied. You girls understand, of course, how hard that is when he comes home with that "Oh, I'm so tired, go away and let me sleep," sort of a feeling.

* * *

Musical shows are usually dedicated to the "tired business man," but entertainment by radio is claimed as the boon of the "weary working woman" who is characterized no longer as "poor working girl" since the "listen-in" privilege came to her.

While awaiting a conference with a busy man the other day, I chanced to mention radio to his stenographer, momentarily enjoying a breathing spell.

"Oh, gee! Ain't it the grandest thing? You know ever since I got my set, I stay home nights and rest up while I listen in. Night after night I used to think I was enjoying myself dancing my feet off or blinking at the movies. But now, I hit the couch, clamp on the ear muffs and tune her in. This gives my feet and eyes a chance to get rested, you see, and transfers the strain to my ears.

"Believe me, I take it easy nights since radio broadcasting got so good. I know the announcers by their first names and their calls like the typewriter keys. When I get sleepy I turn her off and slide into dreamland."

The Radio Primer

For Thousands of Beginners Who Are Coming Into Radio Circles

Weekly A B C of Radio Facts and Principles Fully and Clearly Explained

By Lynn Brooks

WHAT is the difference between series connection and parallel connection of batteries?

When batteries are connected in series the voltage is that of one cell multiplied by the number of cells, but the amperage is that of any one of the cells in the group. When batteries are connected in parallel, the voltage is that of any one of the parallel groups, but the amperage is the sum total of one cell multiplied by the number of cells in the group.

* * *

When should series connection be employed?

Series connection should be used when voltage, or pressure of current, is desired and not amperage.

* * *

When should parallel connection be employed?

If amperage, or quantity of current, is desired from batteries they should be connected in parallel.

* * *

How should dry cells be connected to operate the WD-11 for long life?

As the tube in question only takes 1.5 volts, it is necessary to hook up the cells in parallel. As the life of the batteries is three times as long when two cells are hooked in parallel, it is advantageous to connect them in this way.

* * *

Can six-volt tubes be operated by using dry cells connected in series?

If the tubes are to be operated over a short period of time they can be operated by connecting four dry cells in series, or eight cells in series parallel, but the life of the batteries will be so short that they will last only a very few hours.

* * *

Is it possible to increase the selectivity of a receiver by the use of variable condensers?

By placing a condenser in either the antenna or ground lead of a receiver, a set may be made to tune closer; but if it is not selective, the condenser will not help very much. When a set tunes broadly the general trouble may be credited to distributed capacity, which cannot be alleviated by introducing additional capacity. It is much more efficient to tune a set by inductance than by capacity.

* * *

They use the expression "normal rate of discharge" when talking about storage cells or accumulators. Please explain it.

This expression is meant to express the number of amperes that safely can be drawn from the cell without injury to the plates. To obtain this value, divide the ampere-hour capacity of the cells by the hour rating.

* * *

What is the cause of sulphating of storage cells?

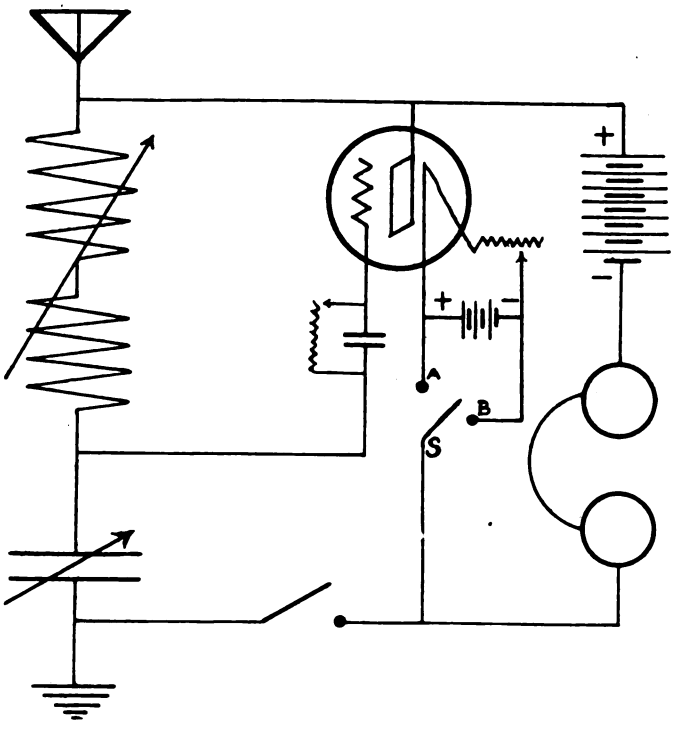
Sulphating is a term applied to a cell when a snow white deposit is formed on the plate. It is due to letting the cells stand too long on discharge, or from serious over-charging.

A 2-in-1 Receiving Set

By S. F. O'Bryan

THE accompanying diagram shows the hook-up of a receiving set designed to work either with or without an aerial. When an aerial is used, switch "S" is placed on point "B" and the switch in the ground lead is closed giving a modified form of ultra-audion circuit that gives wonderful results. The variable condenser then tunes extremely sharp and the grid leak requires close adjustment to obtain the best results.

During heavy spark interference, the antenna may be dispensed with. Switch "S" is then changed to point "A," the other switch is opened, and we have an old tried and true no-aerial circuit that will bring in 'phone and CW through a thunder storm, although the range is, of course, much less than when the first method is used. The inductance between plate and grid now tunes sharply, while the variable condenser and grid leak are less critical.



Hook-up for receiving set to work with or without an aerial.

The average amateur will have no difficulty in making and using this little set as standard parts may be utilized throughout. The variable condenser may have either 23 or 43 plates, and would preferably have a vernier adjustment. The grid condenser and the batteries will be determined by the type of tube used, while the inductance may take any convenient form so long as it can be tuned sharply. A variometer, or a variocoupler with its windings connected in series, will both give good results, but the writer obtained the best results by using two spider-web coils, each wound with 45 turns of stranded wire. This wire was made by twisting six strands of No. 36 wire together, but regular "Litz" would undoubtedly be better. The coils were connected in series as shown, and mounted in the conventional manner to give a variometer tuning effect.

The experimenter who builds this set will find that by using a 1½ volt tube and spider-web inductances as recommended, he can have a remarkably efficient outfit that will be small enough to make a practical vacation time traveling companion.

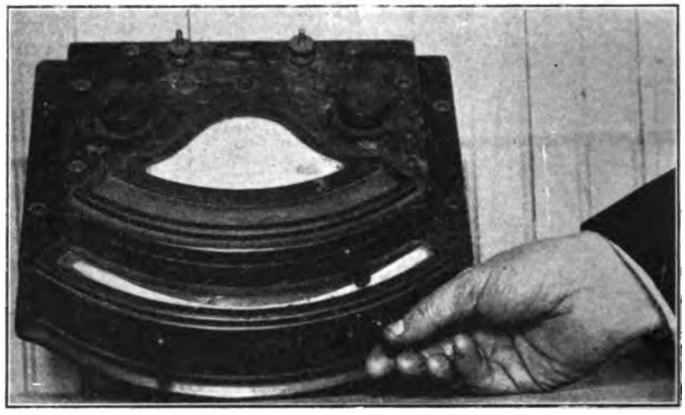
Ubiquitous Camera Me
to Get Radio

(C. Photonews, N. Y.)

Here's an idea put forward by Pierson Mapes. A honeycomb coil in inductive relation with a variometer in a single circuit receiver, and you never have trouble making the signals come pounding in.

(C. Fotograms)

Here it is fellas, the radio set that didn't cost a single penny. Herbert M. Richardson, Minneapolis, Minn., recently made a set out of spare parts as follows: Top of a salad box, six paper fasteners, two paper clips, one safety pin, a piece of galena and some spare wire laying around. Well, when you can go out in the back yard and pick up a radio set, there is no reason for people shying at the very thought of buying one. If you haven't got a back yard, ask your nearest neighbor and maybe he will oblige you by letting you "hunt up a radio set."

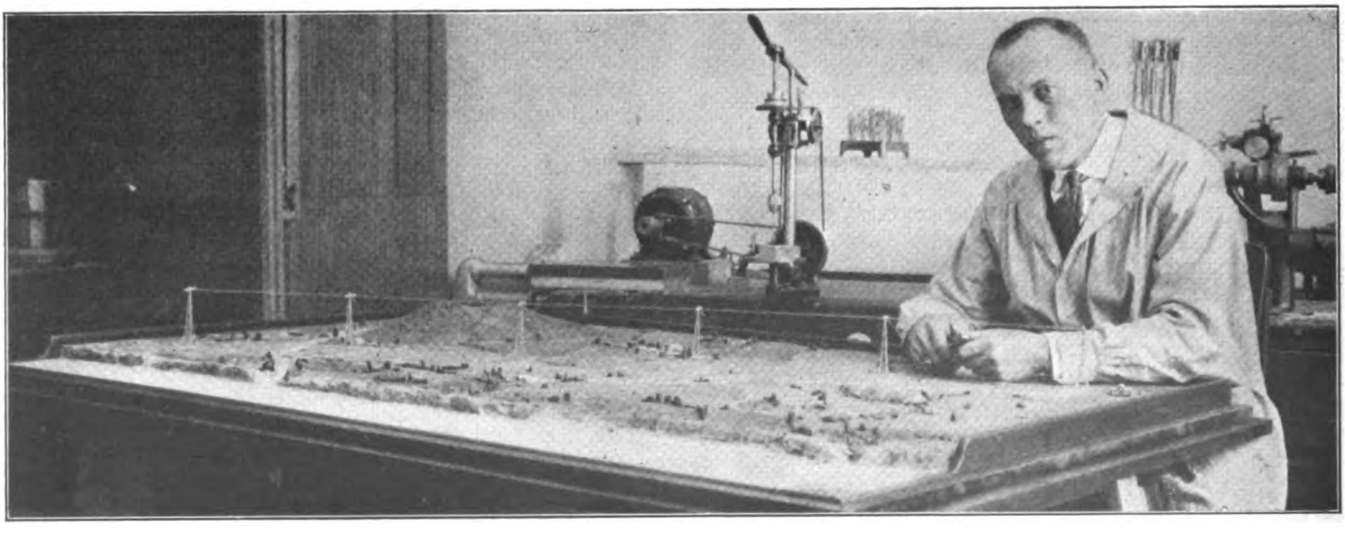


(C. Photonews, N. Y.)

Radio Fans, this is a radio receiver of the vintage of 1904, and was thought at that time to be the very height of perfection. It was used by the U. S. Navy. It is called the Massie "resonophone" and is a three-slide tuner with crystal detector. How different is this dusty antique from the efficient tuners and regenerative sets of today. The only question is, will ours be looked upon in the same manner 20 years from now.

(C. International Newsreel)

Mr. Newton Hill, of Piqua, Ohio, although confined to his bed for 13 years with rheumatism, is not helpless in every sense of the word. He is known as the "Magazine Man" because of the fact that he solicits magazine subscriptions via mail and makes a good living. He recently had a powerful receiver installed to keep his quiet hours pleasantly occupied.



(C. International Newsreel Photo)

A model of the Radio Corporation's high power transatlantic radio station at Rocky Point, Long Island. The model is built on the scale of one inch to 100 feet, and shows the lofty antennae towers, power house and an exact replica of the landscape, even to the trees. The model will be exhibited at the Gothenberg Tercentenary Exposition in Sweden, and is to be used as a model for a station to be erected there.

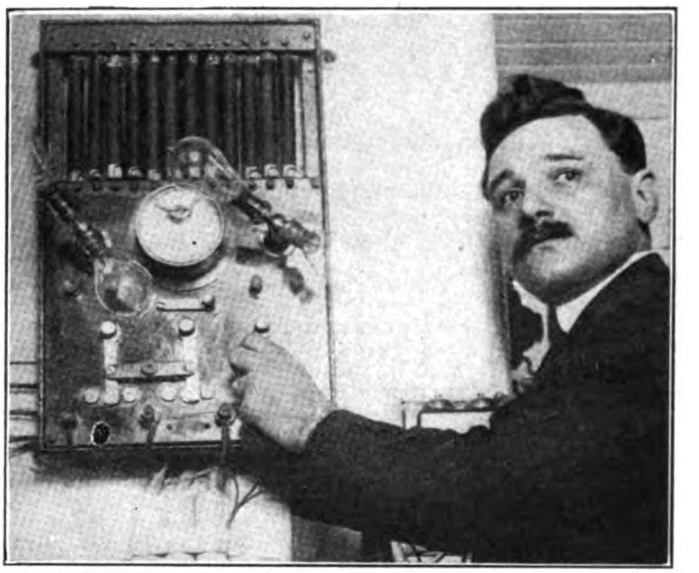
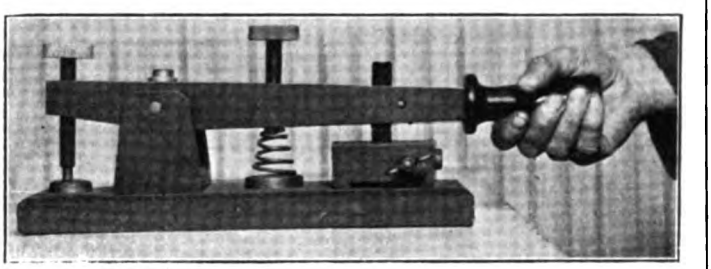
(C. International Newsreel)

Fellows, meet F. H. Schnell, traffic manager of the ARRL Eastern District! The league has just launched a plan to record interference of all kinds on broadcast waves between 360 and 400 meters every evening from 7 to 10:30 and will have the co-operation of 300 of the best known amateurs who will act as observers and file their reports. If your transmitter isn't "kickin' right" on 200, you'd better watch out, or F. H. will get his Wouff Houng out and chase you around the block.



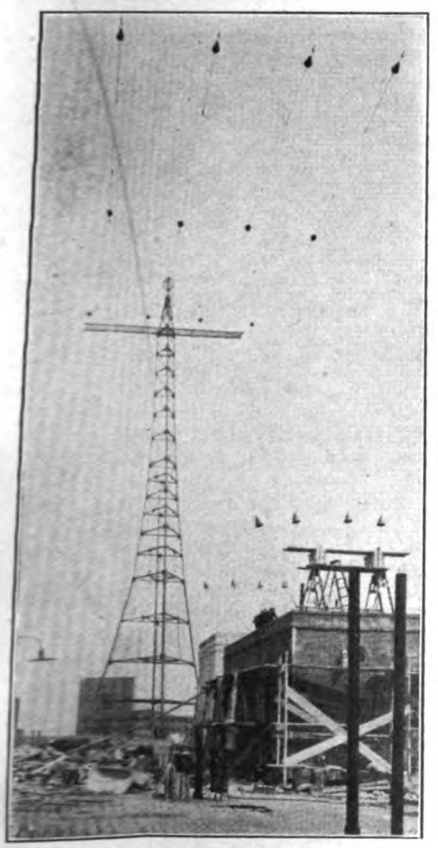
(C. Photonews)

Emergency panel on board the S. S. "Rochambeau" which supplies the set from storage cells in case of accident to the regular ship current which normally operates the set.



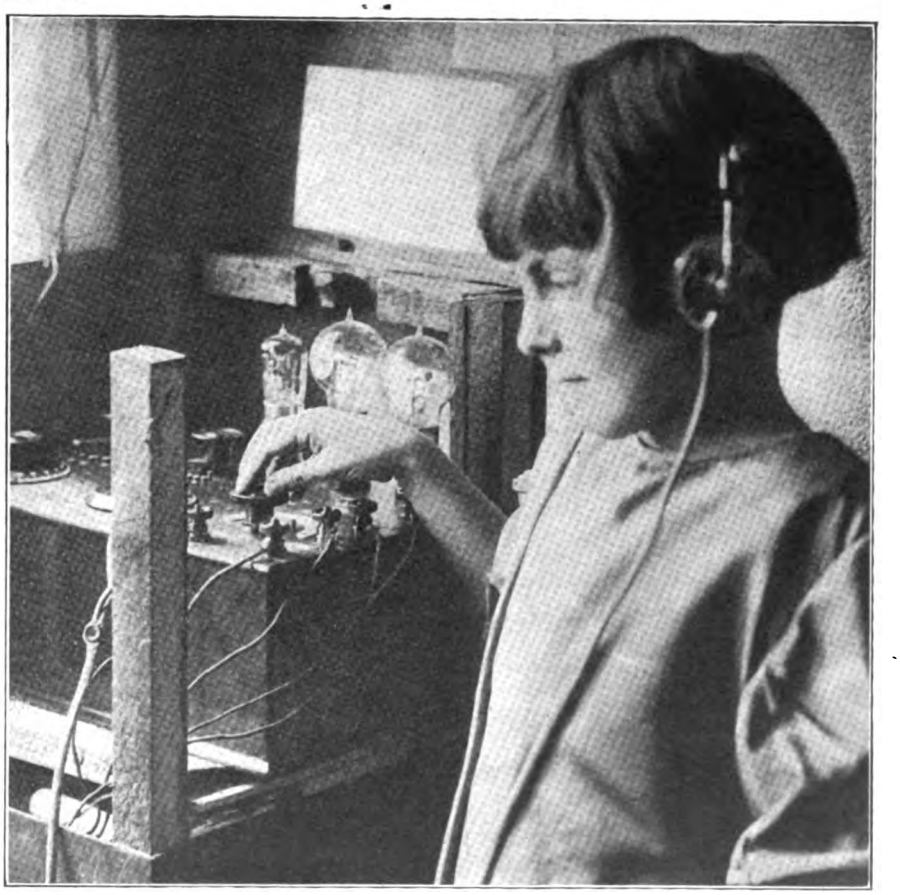
(C. Photonews, N. Y.)

This funny looking key once was the latest thing in the field of wireless. It is one of the old time pump keys and had to be worked in the manner shown. How different from the little arc-proof key of today which handles all kinds of current without sticking!



(Radio Corporation of America)

The completed antenna system at Aeolian Hall, New York. Two separate groups of wires will be used in connection with two transmitters making possible simultaneous transmission on two different wave lengths.



(C. Underwood and Underwood)

Little Miss Sheila Caulfield, of London, England, whose life was saved after a serious operation because her father told her that "Uncle Arthur," of the London broadcasting station, wanted to talk to her over the radio. The doctors attribute her marvellous fight for life to her desire to hear "Uncle Arthur" talk to her on her own radio set.

Answers to Readers

1. *Should the condensers in the article published by C. White in* RADIO WORLD *for March 24, 1923, be .25 mfd. or should they be .00025 mfd.?*

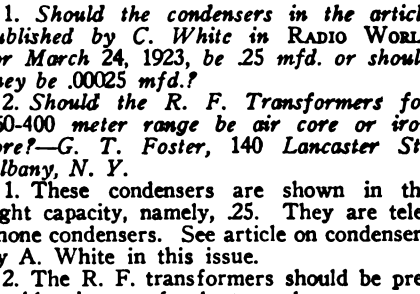
2. Should the R. F. Transformers for 360-400 meter range be air core or iron core?—G. T. Foster, 140 Lancaster St., Albany, N. Y.

1. These condensers are shown in the right capacity, namely, .25. They are telephone condensers. See article on condensers by A. White in this issue.

2. The R. F. transformers should be preferably air core for best results.

* * *

Is there any manner in which a crystal detector can be used with a variometer and variable condenser? — Malcolm Douglas, Webb, Okla.



Hook-up requested by Malcolm Douglas, Webb City, Okla., using a coupler, variometer and crystal detector.

You can incorporate the appartus you mention in the hook-up given herewith.

* * *

1. *Does the Western Electric Co. make a five watt power or transmitting tube?*

2. In hook-ups where they specify a .0005 variable condenser, can I use a .001?

3. Can the Western Electric 216 A tube be used in power amplifiers and what plate voltage can be used on them?—A. Gilburg, 1319 N. Chestnut Street, Spokane, Wash.

1.-3. There is a tube called the 216 A, manufactured by the Western Electric Co. that can be used as a 5 watt tube, and this tube is also the one used on the power amplifiers. When used as a power amplifier tube, 60 to 90 volts is used on the plate.

2. Where a .0005 variable condenser is specified, you can use a .001, but you will obtain finer tuning by the use of the smaller condenser.

* * *

1. *Would it be necessary for two amateurs living in the country to have licenses for operating transmitters made out of two Ford coils, the sets to be used solely for the purpose of learning the code? We live a mile apart.*

2. What apparatus would be necessary for this purpose?

3. Is there a flow of current from the B battery when the filament is extinguished?

4. What is the advantage of the honeycomb coil sets over the variocoupler variometer type?

5. Where are stations 9YS and 5XZ located?—Kenneth H. Jones, London Mills, Illinois.

1. It is necessary to have a license wherever signals are transmitted, no matter what apparatus is used.

2. The apparatus necessary will be a battery, or other source of current, key, Ford or spark coil, helix or tuner, condenser.

3. There is no flow of current when the filament is turned off.

4. The advantage of the honeycomb coil sets over the variometer type is flexibility, as the wave range is not limited to a comparatively small band, but may be varied at the listener's will from 150 to 25,000 meters.

5. Station 5XZ is listed as St. Charles College, Grand Coteau, La. Station 9YS is listed as Wesleyan University, Illinois.

* * *

1. *Can Cunningham 301A tubes be used in reflex circuits as shown by Mr. Thompson in your magazine?*

2. Can jacks be employed to cut out tubes in case reception is too loud?

3. Can the 400 ohm and 2,000 ohm resistances be purchased on the market?

4. What make of radio-frequency transformers would you recommend?—Thomas McLaren, Jr., 129 Pearl Street, Boston, Mass.

1. These tubes can be used as the amplifiers, but where a tube is used as a detector it is best to use a soft tube.

2. No. In order to accomplish this you would have to use an automatic switching system, because the detector must always be the last tube, and every circuit would have to be changed if you intended using fewer tubes.

3. These resistances can be purchased.

4. We do not recommend competitive makes of apparatus through these columns, but buy the best you can and be sure of your results.

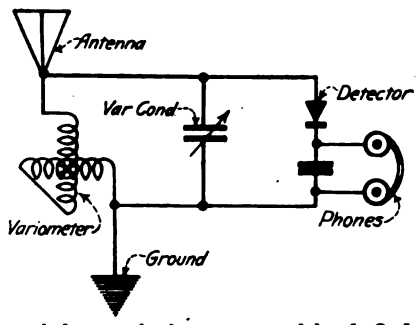
* * *

I want a hook-up for two WD-11 tubes which will bring in the distance stations. What parts are necessary for this set?—Jack D. Leseman, Charleston, S. C.

We refer you to RADIO WORLD for January 27 where you will find the information you desire on page 5 under the heading "How to make a two tube DX set" by John Kent. This also contains a list of the necessary parts.

* * *

Kindly furnish me with a hook-up for the following apparatus: One variocoupler, one variometer, two variable condensers, crystal detector, phone condenser, phones.—John O. Lee, Box 573, care of PSC, Davenport, Ia.



Crystal detector hook-up requested by J. O. Lee using a variometer as a tuner.

The hook-up you request is published herewith. Two condensers are not necessary.

* * *

What type of tube should be used for the Flewelling circuit? Can a Cunningham 301A be used? What plate voltage is necessary?—B. Maxwell Cox, Stafford Springs, Conn., Box 785.

A hard tube should be used for this circuit, such as the 201, or the 216A, or 301A as you suggest. The plate voltage should be 45 to 90 volts.

Radio Corporation of America Has Good Year

THE Radio Corporation of America, in its annual report for 1922, issued for publication last week, reveals the stupendous strides taken during the year toward the development of its vast system of world-wide wireless, outlines its comprehensive program for expansion in all parts of the world, and points out that the public interest in wireless, as shown by the demand for broadcasting, has been almost limitless. The report shows that America leads the world in radio.

To meet the great, popular demand for instruments for reception of broadcast programs the sales department of the Radio Corporation expanded from about fourteen persons to 200, and about 15,000 dealers now handle RCA products. The gross sales for the year were $14,409,557, including the high-power station to the Swedish Government, and seven medium-powered vacuum tube telegraph transmitters for use by the Tropical Radio Telegraph Company in this country, Guatemala, Honduras, Nicaragua, Costa Rica and Panama.

In addition to the increased enthusiasm and efficiency among the personnel of the company there were three outstanding events on the human side of the operation of the Radio Corporation. One was the visit of Senator Marconi, inventor of the first system of wireless communication, as the guest of the corporation; a second was the creation of the new office of Managing Director of International Relations, to which office Mr. Edward J. Nally was elected, and the third was the taking of Mr. Nally's place as President by Major General James G. Harbord, Deputy Chief of Staff of the United States Army, and noted overseas commander and organizer. In the financial section the report says:

"The corporation's financial position has been further strengthened during 1922. Current assets have increased $3,775,984, and exceed the current liabilities by $5,997,966. The current liabilities, amounting to $2,688,941, represent indebtedness for merchandise, materials, and federal income tax. The corporation has no bonded debt.

"The total of plant and equipment, $12,711,348, remains substantially the same as last year, while the reserve for depreciation and obsolescence of plant has been increased by $529,376, and now amounts to $1,347,705. The amortization of patents reserve, after charging patents expired, now stands at $2,405,376, and represents the depreciation to December 31, 1922, indicated by the schedule founded on the life of such patents.

"After providing for depreciation of plant and inventory the operations for the year resulted in a net profit of $2,974,579, which has been allocated, in the main, to reserves for patents and federal income tax, the balance having been applied against organization expense.

"The profits were not sufficient up to December 31, 1921, to meet patent amortization called for by the schedule, and it was necessary to charge $1,666,284 against common stock equity. The total of $2,480,576, transferred from 1922 earnings, provides for 1922 patent amortization and the restoration of the above amount to common stock equity.

"The corporation's capital stock consists of 3,955,974 shares of 7 per cent. preferred stock of $5 par value and 5,734,000 shares of common stock of no par value, against which latter there is shown on the balance sheet an equity of $13,660,163, which is approximately $2.38 a share. No dividend was paid during the year 1922 on either the preferred or the common stock. The 7 per cent. preferred stock becomes cumulative January 1, 1924."

The DX Nite Owls

THE editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

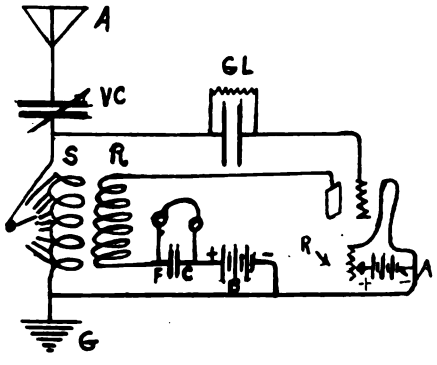
Some DX Dope from the Navy

From C. R. Spicer, U. S. Naval Radio Station, Pt. Loma, San Diego, Calif.

AM enclosing you a hook-up of a set I have been using for a long time and also a little data along with it.

Hook-up is single circuit, but it does the work and gets the results and that in my estimation is what counts. Instruments necessary are as follows:

1 Variocoupler (Rewind Rotor and Stator if necessary).
1 Variable Condenser, 23-plate, .0005.
1 Grid Leak, 3 Megohms.
1 Grid Condenser, .00025.
1 Fixed or By-Pass Phone Condenser.
1 Tube, Socket and Filament Rheostat.



C. R. Spicer's hook-up. He is in favor of rewinding the variocoupler, as described below.

"A" and "B" batteries and pair of good phones.

Get best results with 40 volts on "B" battery.

Am using at present an antenna 150 feet High and 175 long, single wire, but this length and height is unnecessary.

With this hook-up I have received the following stations from the Naval Radio Station here at Pt. Loma, San Diego, Cal.: KDKA, WGY, WOC, WSB, WMC, WWJ, WOR. (During special test with KHJ) WHB, WDAP, WBAF, WFAA, KYW, KSD and others. This list not including Pacific Coast Stations for they are too numerous. Stations mentioned of course do not tear the shack down when they open up, but comfortable reading is assured.

A word about the variocoupler. The Primary tubing is 5 inches in diameter with 60 turns 22 DCC were tapped every 6 turns. The rotor is 4 inches in diameter around with 40 turns of 22 DCC.

Although being within reach of some mighty fine apparatus I have not used any navy instruments.

* * *

Seventy-five Isn't Half Bad as a Beginning!

From Guy Esmond, 13 Grotto Court, Watervliet, N. Y.

I am a subscriber for your magazine, and, wishing to join your Nite Owls am sending what I think is a pretty good record for a one tube set with coupler and condenser:

WNJ, Albany; WSY, Alabama; WOK, Arkansas; WNAC, Boston; WGR, Buffalo; WDAP, Chicago; KYW, Chicago; WMAQ, Chicago; PWX, Havana; WDAK, Connecticut; WDAP, Chicago; WNAJ, Chicago; WDAJ, Georgia; WGM, Georgia; WSB, Georgia; WLK, Indiana; WOC, Iowa; WDAX, Iowa; WKAA, Iowa; WJAF, Indiana; WHAS, Kentucky; WDAD, Kansas; WHAN, Kansas; WEAD, Kansas; WDAF, Missouri; WLAP, Kentucky; WMAK, Lockport; WWI, Michigan; WHAH, Missouri; WIAP, Mass.; WMAF, Mass.; WGI, Mass.; WWJ, Mich.; KOP, Mich.; KSD, Mich.; WMAT, Minn.; WMAJ, Missouri; WMB, Maine; WBZ, Mass.; WLAQ, Mich.; WBAD, Minn.; WEAA, Mich.; WLB, Minn.; WFAQ, Missouri; WCX, Mich.; WHB, Missouri; WEAF, N. Y. C.; WJZ, New Jersey; WOR, New Jersey; WBT, North Carolina; WMAC, N. Y.; WMAH, Nebraska; WHAM, Rochester, N. Y.; WVP, N. Y. (Bedloes Island); WAAM, New Jersey; WLAD, Nebraska; WRW, Tarrytown, N. Y.; WJAX, Ohio; WLW, Ohio; WLAL, Oklahoma; WWB, Ohio; WEAO, Ohio; KDKA, Pittsburgh; WFI, Philadelphia; WIP, Philadelphia; WCAU, Philadelphia; WCAE, Pittsburgh; WOO, Philadelphia; WQAA, Parkersburg, Pa.; KQV, Pittsburgh; WDAR, Philadelphia; WEAN, Providence, R. I.; WGAM, S. Carolina; WGY, Schenectady, N. Y.; WRL, Schenectady, N. Y.; WHAZ, Troy, N. Y.; WDAA, Tenn.; WMZ, Tenn.; WCM, Austin, Texas; WDAG, Amarillo, Texas; WHAJ, W. Virginia; WEAE, Virginia; WIAO, Wisconsin; WHA, Wisconsin. I have been working my set for five months and have heard these stations quite a few times.

Hitting Them on "The Fairway"

From C. Cutbell, 112 Chatterton Parkway, White Plains, N. Y.

THE enclosed "Radio Golf Score" record was made by me on the evening of Feb. 22, 1923. I am using an "Aerola Sr." with one-step of A. F. amplification, and I think this one "beats 'em all." As can be seen I average 6,000-8,000 miles per night.

Time, First Half, 7:30-8:30—7:30, WJZ, Newark, N. J., 50 miles; 7:35, WEAB, New York, N. Y., 35; 7:40, WMAB, Round Hill, Mass., 200; 7:50, WLAB, Carrollton, Mo., 1,075; 7:55, WPO, Memphis, Tenn.,* 1,000; 8:00, WOR, Newark, N. J., 50; 8:05, WHAZ, Troy, N. Y., 200; 8:10, WWJ, Detroit, Mich., 600; 8:12, KDKA, Pittsburgh, Pa., 375; 8:15, WQY, Schenectady, N. Y., 175; 8:17, WBZ, Springfield, Mass., 175; 8:20, WCAE, Pittsburgh, Pa., 375; 8:25, WEAN, Providence, R. I., 150; 8:30, KYW, Chicago, Ill., 800 miles.

One-half hour intermission.

Time of Second Half, 9:00 to 10:30—9:00, KSD, St. Louis, Mo.,* 1,100 miles; 9:07, WOC, Davenport, Iowa, 1,100; 9:15, WSB, Atlanta, Ga., 800; 9:20, WOAP, Chicago, Ill., 800; 9:25, WJAX, Cleveland, O., 600; 9:30, WHAS, Louisville, Ky., 700; 9:40, WJAR, Providence, R. *Stations heard first time.

MAGNAVOX Pioneers in the Radio Field

IT was in 1913 that the Magnavox electro-dynamic receiver made its first public demonstration, when telephone communication was held between Denver and New York—a revolutionary advance.

The rise of radio broadcasting found Magnavox apparatus already perfected and in successful use.

R 2 Magnavox Radio with 18-inch horn

THIS instrument is intended for those who wish the utmost in amplifying power: for large audiences, dance halls, etc., but requires only .6 of an ampere for the field.

Price, $60.00

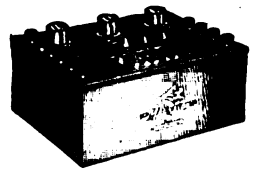
R 3 Magnavox Radio with 14-inch horn

SAME in principle and construction throughout as Type R-2.

Is ideal for use in homes, offices, amateur stations, etc.

Requires one ampere field current from your filament battery.

Price, $35.00



Magnavox Power Amplifier—Model C

CAN be used with any "B" Battery voltage which the power tube may require for best amplification.

AC-2-C, 2-Stage $55.00
AC-3-C, 3-Stage $75.00

The facilities and experience back of each piece of equipment bearing the Magnavox trade mark are unrivalled anywhere in the world.

Magnavox products may be had of good dealers everywhere.

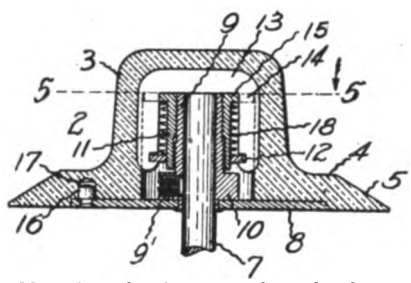
Latest Radio Patents

Actuator for Electric Appliances

No. 1,446,652: Patented Feb. 27, 1923. Patentee: Shiras Morris, Hartford, Conn.

THIS invention relates to what might be broadly termed an actuator for an electric appliance, such as is utilized in wireless work. Such an appliance that is in common use involves a spindle, which is turned by an actuator or dial.

There is in every-day use a wireless cabinet equipped with a spindle with which is associated a knob. This knob in the old structure is attached to its spindle by a binding screw, which is exceedingly objectionable in that it left a metal part exposed. It has been essayed to cover the knob by a cap, which is usually of the same composition as that of the knob, the two parts being usually detachably associated by interengaging threads so as to present what might be considered a duplex cap or dial for a spindle. I provide an actuator or dial for a spindle in one piece from suitable composition, and its exterior has no objectionable projections, yet, by virtue of the invention, when such an actuator is connected with a spindle the latter can be rotated readily



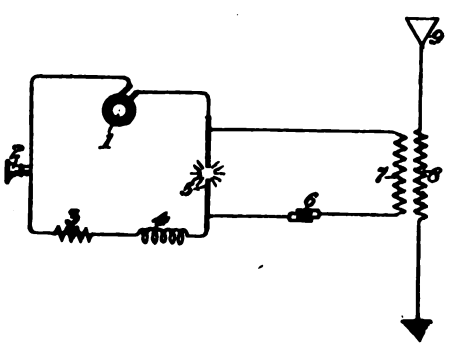
Morris' insulated actuator for radio electric appliances.

when desired—for instance, in tuning—and it also may be quickly taken from the spindle.

System of Ether Wave Control

No. 1,447,779: Patented March 6, 1923. Patentee: John Hays Hammond, Jr., Gloucester, Mass.

Some of the objects of this invention are to provide an improved transmitting station



Diagrammatic representation of John Hayes Hammond, Jr.'s, system of ether wave control.

for radiant energy; to provide an improved receiving station for radiant energy; to provide a transmitting station, including means for continuously emitting electro-radiant waves of constant amplitude at high frequency, and a device for increasing the amplitude of certain of said waves at will in response to and in accordance with sound waves in combination with a receiving station, including a telephonic receiver responsive to said waves of increased amplitude, and a signaling device unresponsive to said waves of constant amplitude, but responsive to said waves of increased amplitude; and to provide other improvements.

Plural Modulation and Demodulation Circuits

No. 1,447,284: Patented March 6, 1923. Patentee: Lloyd Espenschied, Queens, N. Y.

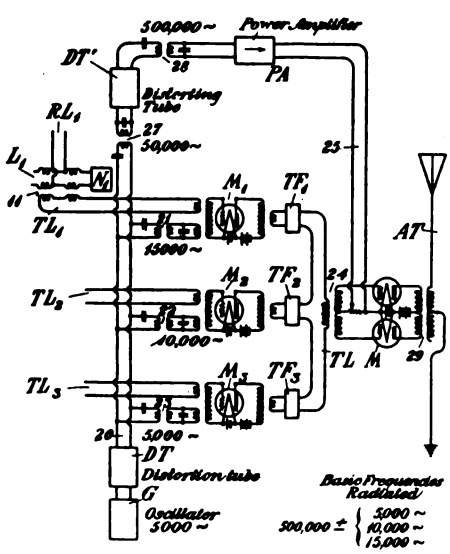
This invention relates to the transmission of signals and more particularly to systems for the multiplex transmission of radio signals.

One of the features of the invention resides in improved methods and means for securing selectivity between a plurality of signaling channels.

Another feature of the invention relates to methods and means whereby the interval between successive signaling channels may be reduced to a minimum.

Still another feature of the invention has reference to the provision of means and methods whereby the frequency intervals between signaling channels may be fixed or determined either at the transmitting station or receiving station, or both.

These features, together with other features of the invention more fully hereinafter appearing, are realized in a method of operation whereby multiplex channels are collected at the sending station and separated at the receiving station at frequencies which are low, compared with the frequencies used in actual transmission between stations. The essential principle underlying this method is that of a frequency step up and a frequency



Illustrating Espenschied's plural modulation and demodulation circuit invention.

step down of a plurality of channels in common, in accordance with addition and subtraction of frequencies by modulation.

A Two-Way Conversation Over 2,000 Miles

By Jeffrey J. Dingman

CFCN, the radio broadcasting station of the W. W. Grant Radio Ltd., at Calgary, Alberta, Canada, which recently accomplished the remarkable feat of conducting a continuous two-way conversation 2,000 miles overland with WHAZ, Troy, New York has a modulating output power of 2,000 watts. When the record breaking conversation with Troy was held Mr. Grant was operating under difficulties and on only 1,000 watts output, and with a generator which has just undergone repairs and was working at only 75 per cent of the full power.

Operation of the rejuvenated set, now one of the most powerful on the continent, was delayed by a devastating fire which destroyed the plant of the W. W. Grant Radio Ltd. CFCN, however, is now equipped with four 500 watt tubes, which were especially manufactured in Montreal, as well as with a specially designed amplification system carrying two 50 watt tubes. A new generator has also been installed and the power of the station has been multiplied four times.

Peculiarly enough, in spite of the vision which might arise in the reader's mind, CFCN is no pretentious establishment. It is a little shack situated on Crescent Heights, in the north end of the city of Calgary, and at a high elevation. Prominent radio engineers from all over the continent who have visited the station here have been amazed to find lacking that which they anticipated, a monumental establishment, with ornate reception rooms and rooms for the talented artists who nightly provide the entertainment for radio enthusiasts the continent over.

The receiving set used to pick up signals from WHAZ, the broadcasting station of the Rensselaer Polytechnic Institute at Troy, on the night of January 12 last when the feat was accomplished, is a Grant-Northern Electric, four tube set, with two stages of radio frequency, one detector and one audio frequency tube. The writer was at the station on the morning of January 13 and could easily hear WHAZ with the headphones held more than two feet away. Hundreds of Calgary and Alberta radio enthusiasts advised CFCN by long distance telephone that they had picked up snatches of the broadcast from WHAZ, while of course they heard the CFCN broadcast in its entirety.

Hundreds of letters poured into the station following the record breaking conversation, one coming from a resident of the Bronx, New York City, who heard Mr. Grant and the Rensselaer Tech both on the night of the record breaking talk. Another came from Alaska, while the majority were from the provinces of Canada and the Western United States.

Achievement of this feat marked an epoch in radiophone broadcasting and established a record for Canada and the United States. If this could be done while CFCN was operating under difficulties and on half of its present output, it is considered that much more marvellous achievements can be attained. At the present time Mr. Grant is negotiating with several far distant stations with a view to arranging a test which will shatter his own record.

W. W. Grant was former chief of the radiophone station of the Canadian government at High River, Alberta, and served with distinction in the European war, having acquired several patents for inventions tending to improve radiophone receiving apparatus, which were utilized to advantage on the battlefields of France. At present he is also operating CHBC, The Morning Albertan station at Calgary.

Solution for Broadcasting Difficulties Offered

AN advanced step to eliminate interference between broadcasting stations was taken when the "power-staggered-wave-length-broadcasting plan" was presented by the National Radio Chamber of Commerce to the Hoover conference last week in Washington.

The National Radio Chamber of Commerce has been studying the broadcasting situation for over a year. At the public hearing the power plan was recommended almost in its original entirety, being one of the most constructive suggestions submitted, and meeting with general approval.

Briefly, the "power-staggered-wave-length-broadcasting plan" contemplates the use of three major bands of wave lengths. Broadcasting would be divided into three main divisions, according to the type of program furnished. Programs covering lectures, talks, reports, etc., would be broadcast on a particular wave length band. Classical musical programs would be broadcast on another wave length band, while popular musical programs would be confined to still another wave length.

In addition, the country would be divided into broadcasting districts. Broadcasting stations would operate simultaneously on the three major wave length bands. The plan has been so worked out that there is ample variation in wave lengths, and no two broadcasters will interfere with each other. In fact, three broadcasters may operate simultaneously in one district without interference, as well as several other broadcasters, in accordance with the time schedule arrangements. The idea back of the whole plan is to give the public what they want when they want it. The receiving sets are tuned to the program desired.

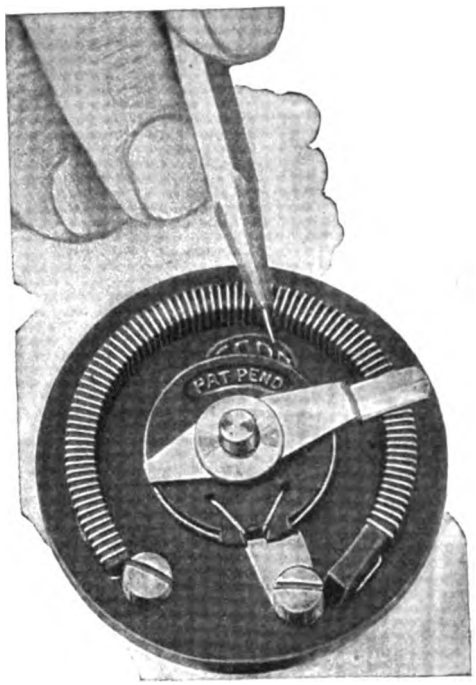
The power plan as recommended by the National Radio Chamber of Commerce was originated by Harold J. Power, of Medford Hillside, Mass. Mr. Power is vice-president of the American Radio and Research Corporation. He was a pioneer in the development of radio, and has devoted much of his time to study of the broadcasting situation, being an active member of the special Broadcasting Committee of the National Radio Chamber of Commerce.

WDAP Proves Its Power in Unusual Way

RADIO history was made recently through the efforts of Thorne Donnelley and Elliot Jenkins, in charge of broadcasting at Station WDAP, Drake Hotel, Chicago. While the letters WDAP are merely a designation by the government for this station alone, they have been most appropriately interpreted as meaning "We Do Atlantic-Pacific" in view of the extremely wide range of "pick up" from this powerful inland station, which has been designated as the official broadcasting station of the Chicago Board of Trade.

On the S. S. "Berengaria," clearing 600 miles a day, which sailed from New York January 30th, Miss Florence McDonald had installed a receiving set. From January 30th to February 4th, every day at appointed hours, messages were flashed vocally by Mr. Donnelley, heard and recognized aboard the "Berengaria."

Each time an erroneous statement regarding the length of the Berengaria would be made (newspaper men picked the number haphazard out of a hat a few minutes before the broadcasting) and each time came back the answer from the steamship giving the incorrect length as well as the correct length, now 250 miles out, then 725 miles out, again 1286 miles out, again 1824 miles and so on until the maximum distance was reached. This was the first successful attempt to reach a voyaging ship from an inland station, on a predetermined schedule. No special tubes were used by the Drake station nor in the receiving set.



Fada Rheostats and Potentiometers

Over a million and a half FADA receiving tube rheostats alone were manufactured during 1922.

FADA vernier rheostats and potentiometers are fast becoming the favorite with the radiophans who construct their own receivers.

The Suneco Tube Adapter

A DEVICE which permits the elimination of storage batteries and rewiring and permits the use of the WD-11 tube is provided in the Suneco tube adapter. The new model is known as Type A-D 112, has no soldered connections, and is made of the best grade moulded condensite. It will adapt the aeriotron WD-11 tube to any standard socket without the necessity of rewiring. It also allows the tube a half-inch clearance, tending to avoid breakage and permitting the use of the tube in a greater number of sets.

Preliminary Injunction Denied in Radio Patent Action

Federal Judge Rellstab at Newark, N. J., has denied an application for a preliminary injunction made by the Westinghouse Electric and Manufacturing Company against the Radio Craft Company, Inc., and the De Forest Radio Telephone and Telephone Company, both of Jersey City. The Westinghouse company alleged that the two companies had infringed upon certain radio patent rights owned by it. The court fixed May 8 as the date for hearing a motion for permanent injunction and directed the defendants to to file a joint bond of $10,000 to indemnify the plaintiff company against loss through patent infringement.

Radio and the Coast Guard Save a Lightship Man

RADIO, a coast guard cutter, and a lifeboat launched through an unusually rough surf at night were instrumental last week in saving the life of John H. Steel, member of the crew of the Fenwick Island lightship, thirty miles off the southeast coast of Cape May, N. J. Early in the evening a message was received at the naval radio station at Cape May from the lightship stating that Steel had been stricken with acute appendicitis and that his life was in danger. The message was relayed to Captain R. C. Weightman, of the cutter Kickapoo, who immediately put out to the lightship in a sea running high. Steel was swung aboard and taken to the Delaware Breakwater, where Captain Lynch, of the Lewes coast guard station, notified in advance, called out the station crew and brought the lifeboat safely through. A waiting automobile took Steel to the government hospital at Lewes, where an operation was performed. Attending surgeons said later that Steel would recover.

Radio Station Heard 8,000 Miles

TO be heard 8,000 miles is the record of the radio broadcasting station erected by the International Western Electric Company at the Brazilian Centennial Exposition at Rio de Janeiro," said Col. N. H. Slaughter, one of this company's radio engineers just returned from Rio. "Our signals were heard by a government radio station in Honolulu. This is the long distance record for a 500 watt radio transmitter."

This broadcasting station was installed shortly after the opening of the Brazilian Exposition at Praia Vermelha, a suburb of Rio de Janeiro, where the National Telegraphs, the government bureau of communications, had established as an official section of the Exposition, a special building for radio exhibits. The apparatus used is a standard 500 watt radio transmitter identical with that at WEAF, WCC, WSB, and other well-known stations equipped with Western Electric appartus.

The antenna is of a very unusual type. It is a six wire cage antenna extending 500 feet above the station, the upper end being suspended from a cable strung between the tops of two mountains, Urca and Babylonia, near the famous Sugar Loaf Mountain.

The programs broadcast by this station were received at the exposition and amplified by the Western Electric public address system for the enjoyment of the thousands of visitors there.

This station, SPE, was also used in a point-to-point radio demonstration between Rio de Janeiro and Sao Paulo, 225 miles distant. The speeches of the Brazilian Minister of Agriculture and other government officials and music were transmitted to Sao Paulo where they were received and amplified for a loud speaker which made the entertainment audible to the crowds gathered there. This is also a remarkable feat, as the tests were made in summer and in the daytime when radio transmission is most difficult. In addition the country between is exceedingly mountainous and is covered by a thick tropical verdure which absorbs an excessive amount of the energy passed from one station to another. It proved to be the most difficult location as yet encountered by this company's radio engineers. Their findings will prove an interesting page in the history of radio development.

Teaching by Radio to Be Tried Via WJZ

STUDENTS in the Haaren High School, New York City, will have the distinction of being the first to hold a class without an instructor present. Mr. H. W. Leyenberger, an instructor in machine accounting, will be located in the Waldorf Studio of the Radio Corporation—Westinghouse Station WJZ—and will conduct the class in accounting from there.

This novel experiment, which is taking place with the approval and under the auspices of the Board of Education of New York, is for the purpose of showing how radio can become a great factor in the educational field, both from the instruction and administrative viewpoint.

The experiment will take place on 360 meters. There has been installed in the Haaren High School classroom, where there are thirty accounting machines, a receiving set with loud speaker equipment. Mr. Leyenberger will give specific instructions by radio to the class, who will perform the operations indicated. Another receiving set will be located at the Board of Education in the office of the Associate Superintendent, Dr. Clarence E. Meleney, who is in charge of the high school. He and the other superintendents may then listen to this instruction along with many thousands of people equipped with receivers, working at that time.

The GOODMAN is really a high grade instrument, well and sturdily constructed. The PANEL and FANS are GENUINE BAKELITE—the best material known for the purpose.

Auxiliary Condensers

THE operation of radio receiving sets can be improved by the use of a very simple and cheap condenser connected across the telephone receivers and a similar one connected in series with the antenna, according to the Bureau of Standards of the Department of Commerce. Longer waves can be received by the use of a very simple type of loading coil. The coil is particularly useful in connection with the single-circuit receiving set.

The auxiliary condenser which is used in series with the antenna, and the loading coil, may also be used when the crystal detector is replaced by an electron tube detector unit, or when an amplifier is added to the receiving set.

The condenser used in series with the antenna makes it convenient to tune to wave lengths less than 300 meters. The condenser used across the telephone receivers increases the intensity of signals which are received from some radio stations. The loading coil enables the equipment to respond to wave lengths above 600 meters, up to about 3,000 meters. Time signals from high power stations can thus be received. The use of the loading coil also increases the receiving distance of the equipment, because many of the higher power stations use longer waves.

Mr. Albright Points Out an Error

EDITOR, RADIO WORLD; I have just received the March 17 issue of RADIO WORLD, in which you published my article, "How to Build a One-Tube, Dry-Cell Set." I notice that the cut of the circuit shows a connection between the aerial and ground across the inductance coil. It seems that you have reproduced this cut from the pencil drawing, so I must have shown it so. The set will not function if this connection is made; and, in justice to the many fans who will try this circuit out, I wish that you would call their attention to this error.

I have written to about a hundred and fifty fans who have asked me for the circuit, and I have advised them to get RADIO WORLD and read the article.

Thanking you in advance for calling your readers' attention to the error, I remain

Very truly yours,
Englewood, Colo. P. F. ALBRIGHT.
March 30, 1923.

New Offer of Westinghouse Stock

THE Westinghouse Electric and Manufacturing Company, at a directors' meeting held last week, authorized the sale of $14,962,530 additional common stock, which will be offered to stockholders at a subscription price of $53 a share, to the extent of one share of new stock for each five shares now held. The offer will be made to stockholders of record April 16. Payment for the stock must be made in full by May 31.

Guy E. Tripp, Chairman of the Board of Directors, has issued a letter to stockholders, in part as follows:

"Your company has a large amount of unfilled orders on hand, and is taking additional orders in large volume. In addition the directors believe that there will be a still further enlargement in the demand for your company's products, due to the public attention which is now being directed toward hydroelectric developments, steam railroad electrification, industrial electric manufacturing processes, further development of activities in the radio field, and a widening use of electricity for other purposes, all of which would stimulate still greater activity in your various manufacturing lines.

"After applying the proceeds of the sale of the new issue of common stock the net quick assets of the company, as of March 31, 1923, will amount to $105,000,000."

Gen. Harbord Says Production of WD-11 Tubes Is Nearing Demand

Rumors have been spread that the manufacturers of the WD-11 tube have been holding back production and have as often been denied. Gen. Harbord, president of the Radio Corporation of America, last week issued this statement:

"I give you my word there is no truth in that charge. I have heard it before, and there is no basis for it. On the contrary, we are trying to increase the production of the WD-11 tubes as much as possible. Why should we not? We asked for a production of 7,500 a day of those tubes as long ago as the middle of February. They have now reached a production of 5,000 a day, and in about two weeks I hope they will have reached a production of 10,000 a day. Then the demand will be taken care of very quickly. There have been many blasphemous and scandalous things said about us, on the theory that we were holding up production, but I assure you we are doing our best to meet the demand."

General Electric Reports a Tremendous Business

THE annual report of the General Electric Company, as of December 31, 1922, shows total income of $30,794,966, as compared with $28,676,683 in 1921, and net income from sales of $22,736,281, as against $21,676,683. Profit available for dividends was $26,231,019, compared with $21,652,812 in 1921. Cash dividends were $14,073,628, as against $13,409,522 the previous year. This left a surplus in excess of cash dividends of $12,157,391, as compared with $8,243,290 in 1921. Total surplus was $73,167,047.

Net sales billed were $200,194,294, as against $221,007,991 in 1921; but cost of sales declined to $177,458,012, as compared with $199,331,308 the previous twelve months. Orders received were $242,739,527, compared with $179,721,680 in 1921, an increase of 35 per cent. Unfilled orders at the end of the year were $76,220,000, as

YOU DX HAMS!

Have you seen the hook-up with complete panel layout in full size and all constructional details in RADIO WORLD No. 43, dated Jan. 20?

This hook-up actually goes out and drags the distance in, and lays it at your table.

All that is necessary is to lay the full-page diagram of the panel on your own panel and drill and mark your holes. Simple, isn't it?

If you haven't this copy, send 15 cents to Radio World, 1493 Broadway, New York, N. Y., and copy will be mailed you. Or start your subscription with that number.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

A Good Thing—Pass It Along!

An especially valuable article is that published in this issue of RADIO WORLD on the construction of a new form of two unit radio receiver. In writing this description of the set as well as in the careful drawing of the plans, the author has taken nothing for granted except to assume that the reader has a slight knowledge of an aerial and knows one radio instrument from another. This article is just the thing for an established amateur to turn over to a comrade who has not a radio set but who is thinking of building one. The more advanced readers of RADIO WORLD can further the common cause by telling prospective amateurs about this interesting article.

How to Drill Holes in Glass

Grind a three-cornered file to a sharp point and use it as a drill after first pouring turpentine on the glass at the point where the hole is to be.

Which are you?

A small timer or do you bat in the Big League?

Do you like to reach over states and pull in the breezy line from the far West or hot stuff from down in Texas, or maybe the business twang of the good old East? Now that you've answered this questionnaire, remember that if you want Distance you want instruments built for Distance.

IF YOU ARE A REGULAR RADIO fan and like to hear the stations in the four corners of the United States come in with a bang, then you will want the Flewelling Circuit. If you do, send 15c for RADIO WORLD, issue of Feb. 24, which contains complete description and directions for the manipulation of the circuit. RADIO WORLD, 1493 Broadway, New York.

MODEL MAKING—By Raymond Francis Yates. A new book for the mechanic and model maker. This is the first book of its kind to be published in this country, and all those interested in model engineering should have a copy. The first eight chapters are devoted to such subjects as Silver Soldering, Heat Treatment of Steel, Lathe Work, Pattern Making, Grinding, etc. The remaining twenty-four chapters describe the construction of various models such as rapid fire naval guns, speed boats, model steam engines, turbines, etc. 400 pages. 301 illustrations. Price, $3.00. The Columbia Print, 1493 Broadway, New York City.

STANDARD ELECTRICAL DICTIONARY—By Prof. T. O'Conor Sloane. Just issued an entirely new edition brought up to date and greatly enlarged—as a reference book this work is beyond comparison, as it contains over 700 pages, nearly 500 illustrations, and definitions of about 6,000 distinct words, terms and phrases. The definitions are terse and concise and include every term used in electrical science. 767 pages, 477 illustrations. (See page 18 for fuller description.) Price, $5.00. The Columbia Print, 1493 Broadway, New York City.

VACUUM TUBE RESULTS WITH A CRYSTAL SET!—Cover distance with a "PT" ULTRA-SENSITIVE CONTACT in your crystal detector. Beats gold and other ordinary catwhiskers. DOES NOT JAR OUT. Using the "PT," Myrle Wood heard over 43 broadcasting stations in a thousand mile radius! Other users testify: "Heard new stations on first adjustment. Has all advantages you claim. Receives music so loud it hurts my ears." The "PT" has received 3,300 miles through static. Price only twenty-five cents. "PT" CRYSTAL CONTACT COMPANY, Box 1641, Boston, Mass.

WIRING A HOUSE. By Herbert Pratt. Shows a house already built; tells just how to start about wiring it; where to begin; what wire to use; how to run it according to insurance rules; in fact, just the information you need. Directions apply equally to a shop. Sixth edition. COLUMBIA PRINT, 1493 Broadway, N. Y. C. Price, 25 cents.

HOW TO BECOME A SUCCESSFUL ELECTRICIAN—By Prof. T. O'Conor Sloane. An interesting book from cover to cover. Telling in simplest language the surest and easiest way to become a successful electrician. The studies to be followed, methods of work, field of operation and the requirements of the successful electrician are pointed out and fully explained. 202 pages. Illustrated. Nineteenth revised edition. Cloth. Price, $1.50. The Columbia Print, 1493 Broadway, New York City.

BUILDERS AND EXPERIMENTERS. Do you know that the Reflex circuit is one of the most interesting circuits to construct? You can not guess how much fun you are missing if you fail to try out at least one of these circuits. See RADIO WORLD issues of Feb. 24 and March 3. They contain two fine articles by W. S. Thompson, with plenty of new Reflex circuits to experiment with. Don't miss these! 15c. a copy. RADIO WORLD, 1493 Broadway, New York City.

TWENTIETH CENTURY BOOK OF RECIPES, FORMULAS AND PROCESSES—Edited by Gardner D. Hiscox. This book of 800 pages is the most complete book of recipes ever published, giving thousands of recipes for the manufacture of valuable articles for every-day use. Hints, helps, practical ideas and secret processes are revealed within its pages. It covers every branch of the useful arts and tells thousands of ways of making money and is just the book everyone should have at his command. The pages are filled with matters of intense interest and immeasurable practical value to the photographer, the perfumer, the painter, the manufacturer of glues, pastes, cements and mucilages, the physician, the druggist, the electrician, the dentist, the engineer, the foundryman, the machinist, the potter, the tanner, the confectioner, the chiropodist, the manufacturer of chemical novelties and toilet preparations, the dyer, the electroplater, the enameler, the engraver, the glass worker, the gold-beater, the watchmaker, the jeweler, the ink manufacturer, the optician, the farmer, the dairyman, the paper maker, the metal worker, the soap maker and the technologist in general. A book to which you may turn with confidence that you will find what you are looking for. A mine of information up-to-date in every respect. Contains an immense number of formulas that everyone ought to have that are not found in any other work. New edition. 807 octavo pages. Cloth binding. Price, $4.00. The Columbia Print, 1493 Broadway, New York City.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., REQUIRED BY THE ACT OF CONGRESS OF AUGUST 24, 1912.

Of Radio World, published weekly at New York, N. Y., for April 1, 1923.

State of New York,
County of New York, ss.:

Before me, a Notary Public, in and for the State and County aforesaid, personally appeared Roland Burke Hennessy, who, having been duly sworn according to law, deposes and says that he is the Editor of the Radio World, and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are: Publisher, Hennessy Radio Publications Corporation, 1493 Broadway, N. Y. C.; editor, Roland Burke Hennessy, 1493 Broadway, N. Y. C.; managing editor, Stephen L. Coles, 1493 Broadway, N. Y. C.; business manager, none.

2. That the owners are: (Give names and addresses of individual owners, or, if a corporation, give its name and the names and addresses of stockholders owning or holding 1 per cent or more of the total amount of stock): Hennessy Radio Publication Corp., 1493 Broadway, N. Y. C., Roland Burke Hennessy, 1493 Broadway, N. Y. C.; M. J. McArthur, Statler Hotel, Cleveland, Ohio.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of total amount of bonds, mortgages, or other securities are: (If there are none, so state.) None.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear on the books of the company but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear on the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association, or corporation has any interest direct or indirect in the said stock, bonds, or other securities than as so stated by him.

5. That the average number of copies of each issue of this publication sold or distributed, through the mails or otherwise, to paid subscribers during the six months preceding the date above shown is.....weekly. (This information is required from daily publications only.)

ROLAND BURKE HENNESSY,
Editor.

(Sworn to and subscribed before me this 31st day of March, 1923.

KARL E. GOTTFRIED.

Notary Public, New York County. New York County Clerk's No. 301. New York Register's No. 4228. Commission expires March 30, 1924.

Note.—This statement must be made in duplicate and both copies delivered by the publisher to the postmaster, who shall send one copy to the Third Assistant Postmaster General (Division of Classification, Washington, D. C., and retain the other in the files of the post office. The

RADIO WORLD INSPIRES HIGH PRAISE

Editor Radio World:

It is both a pleasure and an honor to congratulate you upon the successful completion of the first year of RADIO WORLD.

We know of no other magazine in the whole wide world that gives so much up-to-date radio news and wireless information as RADIO WORLD. Indeed, we know of only one other weekly wireless publication, and that is the official organ of the Wireless Society of London.

We believe that RADIO WORLD easily stands at the head of all the wireless publications. We are subscribing to twenty of them. We have two subscriptions with you and are proud to maintain our file complete from Volume 1, Number 1 on.

We wish you continued success from a literary as well as a financial standpoint, and it seems to us that anyone interested in radio or wireless, once he has seen RADIO WORLD, should not hesitate to subscribe to it.

Monthly publications are all right, but what radio fan wants to wait a month to read something new?

Yours very truly,
P. C. KULLMAN & CO.
New York City,
March 31, 1923.

British to Investigate Transatlantic Wireless Phone

WITH a view to investigating the possibility of developing commercial wireless telephony across the Atlantic Ocean the Postmaster General of Great Britain has appointed a committee, which includes Admiral Sir Henry Jackson, Major General F. H. Sykes and a number of technical experts, to advise what practical steps may be taken in the premises. The Postmaster General says it is understood the telephone authorities in the United States are willing and anxious to co-operate.

Radio Fan Goes to See Opera After Broadcast

AFTER hearing the broadcasting of the Wagnerian opera "Die Meistersinger" several weeks ago from the Radio Corporation-Westinghouse Station WJZ in Newark, N. J., John E. DeShazo, a Newark fan was so impressed that he decided to see the opera first hand. Here is a case where radio helped to popularize the opera and the sale of tickets for the theatre. Mr. DeShazo bought seats to see "Tannhauser" which was broadcast from WJZ not long ago.

IF YOU ARE INTERESTED IN RADIO YOU NEED THESE BOOKS

RADIO BOOKS THAT HELP YOU

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems

Radio Hook-Ups

By M. B. SLEEPER

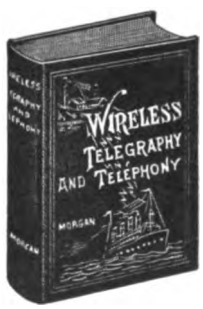
A book that gives you not only clear diagrams for all kinds of telephone and telegraph receiving and transmitting sets, but simple descriptions of each circuit shown and spaces for notes of results obtained.

PRICE 75c.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

There is a peculiar fascination about receiving radio messages from the high-power stations of England, France, Germany, Russia and Italy, as well as those located in the Pacific Ocean and the Oriental countries. Several types of simple receiving sets for this purpose are described, with detectors and amplifiers to accompany them. Suggestions are also given for operating relays and reproducing the signals on a phonograph. Schedules of operating time for high-powered stations are given. In addition, there is some valuable data on home-made wavemeters for testing and experimenting .....PRICE 75c.



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50

Design Data for Radio Transmitters and Receivers

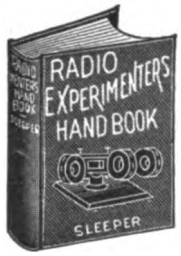
By M. B. SLEEPER

The only book that gives tables and data for designing, receiving and transmitting apparatus so that you need no knowledge of mathematics. It's the first book a beginner buys after he has learned the use of his phone receiver.....PRICE 75c.

Construction of Radiophone and Telegraph Receivers for Beginners

By M. B. SLEEPER

The man who wants to feel the real thrill of accomplishment, and who is not satisfied in the merely making use of what others have done for him, builds his own radio apparatus. Radio men can follow the data in "Radio Phone and Telegraph Receivers" with full confidence, because each piece of apparatus described was first made, tested and found efficient before the final design was accepted. Special receivers, both crystal and audion, are shown in detail. Regenerative circuits as well as audio and radio frequency amplifiers are described with clear photos, diagrams, and working drawings prepared especially for the novice and the man who wants to receive the radio telephone broadcast. A special feature is the phonograph type radio set and the loud speaker. Fully illustrated.....PRICE 75c.

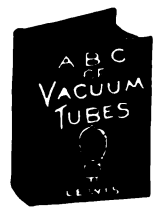


The Radio Experimenter's Handbook

By M. B. SLEEPER

Throughout the preparation of this book, one purpose was kept in mind—Answer the Practical Questions of the "Novice," of the "Beginner," and the more advanced "Student." This book will help in the selection or construction of simple apparatus for the transmission and reception of radio telegraph and telephone signals. In the chapters on radio receivers the simplest crystal, the simple audion, and the regenerative types are described in quite some detail. The question of antennas, both for transmitting and receiving, are taken up. A good many helpful suggestions are given which will be of considerable aid to the experimenter. 16 chapters. Fully illustrated.

PRICE $1.00



The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

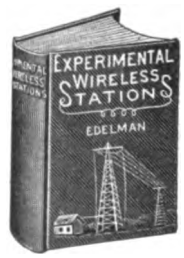
Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

How to Make Commercial Type Radio Apparatus

By M. B. SLEEPER

This book describes in detail many commercial types of spark and vacuum tube telephone transmitting and telegraph and phone receiving equipment of all kinds. The experimenter will be able to get a world of ideas for the design and construction of his next piece of radio equipment from the very clear descriptions and the 98 clearly illustrated figures.....PRICE 75c.



Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations.....PRICE $2.00

Radio Engineer for Bureau of Standards

DR. AUGUST HUND, of Berkeley, Cal., has been appointed electrical engineer in the Radio Section of the Bureau of Standards, Department of Commerce. Dr. Hund is a Doctor of Engineering, having geen graduated from the Technische Hochschule, Carlsruhe, in 1913. He served two years under Dr. Steinmetz in the General Electric Company and is author of a technical book on frequency measurements. For the past several years he has been doing graduate work at the University of California.

Adams County Radio Club

A RADIO club under the name of Adams County Radio Club has been organized in Gettysburg, Pa. The following officers were elected: President, Earl G. Ports, operator of Station 3BHY, Gettysburg College; vice-president, G. E. Slaybaugh; secretary-treasurer, H. W. Baker, operator of Station 3CBJ, Gettysburg, Pa. The club will hold weekly meetings in the physics lecture room of Gettysburg College. Papers by various members will be read, and code instruction given. Study and design of radio apparatus and other problems of importance in radio work will be among the activities of the organization. The two radio telephone stations operated by members of the club—3BHY, with 50 watts power, and 3CBJ, with 10 watts power—will be used to further club organization and interest. The club would be pleased to have reports from those hearing these stations.

Combination Socket and Rheostat — Eliminates Wiring

A deivce for which amateurs and professionals have long been waiting.

A combination V. T. Socket and Rheostat for panel mounting which entirely eliminates separate leads between socket and rheostat and at the same time provides a panel-mounted socket without the use of additional brackets, thus materially simplifying the installation and hook-up.

Cat. No.	Type	Ohms	List Each
2007	A-1	5 with Knob and Pointer	$2.00
2008	A-2	5 ¼" Shaft without Dial	2.00

Unless otherwise specified, Type A-1 will be supplied.

REINARTZ CIRCUIT
EVERY PART COMPLETE

1 Reinartz wound coil, 1 tube socket, 1 rheostat, 1 23-plate .0005 MFD variable condenser, 1 13-plate .00025 MFD variable condenser, 3 inductance switches, 16 switch points and nuts, 4 switch stops and nuts, 2 3" dials, 8 binding posts, 1 variable grid leak, 1 .002 MFD phone condenser, necessary bus bar wire, 1 high grade Radion panel and diagram and complete instructions..... $10.00

FLEWELLING CIRCUIT
EVERY PART COMPLETE

2 honeycomb coils, 1 2-coil mounting, 2 coil plugs, 3 .006 condensers, 1 variable grid leak, 1 grid leak 1 23-plate .0005 MFD variable condenser, 1 Vernier rheostat, 1 tube socket, 8 binding posts, 20 feet bus bar wire, 1 high-grade RADION panel, 1 3" dial and the Radio Digest Booklet on Operation and Construction of Circuit $11.00

CONDENSERS

8 Plate Variable; value, $1.75	$1.05
13 Plate Variable; value, $2.50	1.29
23 Plate Variable; value, $3.50	1.85
43 Plate Variable; value $4.50	1.85
13 Plate VERNIER; value, $5.50	$3.75
23 Plate VERNIER; value, $6.00	4.00
43 Plate VERNIER; value, $6.50	4.25
Reinartz Coils; value, $2.50	1.75
V. T. SOCKETS—Nickeled brass sleeve, composition base; value, $1.00; special at	.59
Ball Bearing inductance switch; value, 75c; special at	.39
Honeycomb Coils, 50 turns, mounted	.95
Honeycomb Coils, 75 turns, mounted	1.00
Double Coil Mountings	2.45
Triple Coil Mountings	3.85
Audio-Freq. Transformers	2.75
FILAMENT RHEOSTAT — Condensite base; value, $1.10; special at	.79
FILAMENT RHEOSTAT with 2½" dial; value, $1.50; special at	89c
Potentiometer with knob; value $1.75; special at	1.00
Potentiometer with 2½" dial; value, $2.15; special at	1.15
BEST QUALITY JACKS, Single circuit; value, 65c; special at	.39
Double circuit; value, 90c; special at	.45
VARIOCOUPLER — Celoron condensite and Litz Wire wound secondary; value $4.50; special	3.25
THREE-INCH DIALS—Unbreakable—heat resisting composition—high finish; special	.39

VOLUME THREE OF

RADIO WORLD

[Entered as second-class matter, March 28, 1922, at the Post Office at New York, N. Y., under the Act of March 3, 1879]

A Weekly Journal, Published Every Wednesday and Dated Saturday, by Hennessy Radio Publications Corporation from Publication Office, 1493 Broadway, New York, N. Y. Telephone: Bryant 4796.

Vol. III, No. 4. Whole No. 56 | April 21, 1923 | 15c. per copy, $6.00 a year

Hook-up of the Haus Transmitter

By John Kent

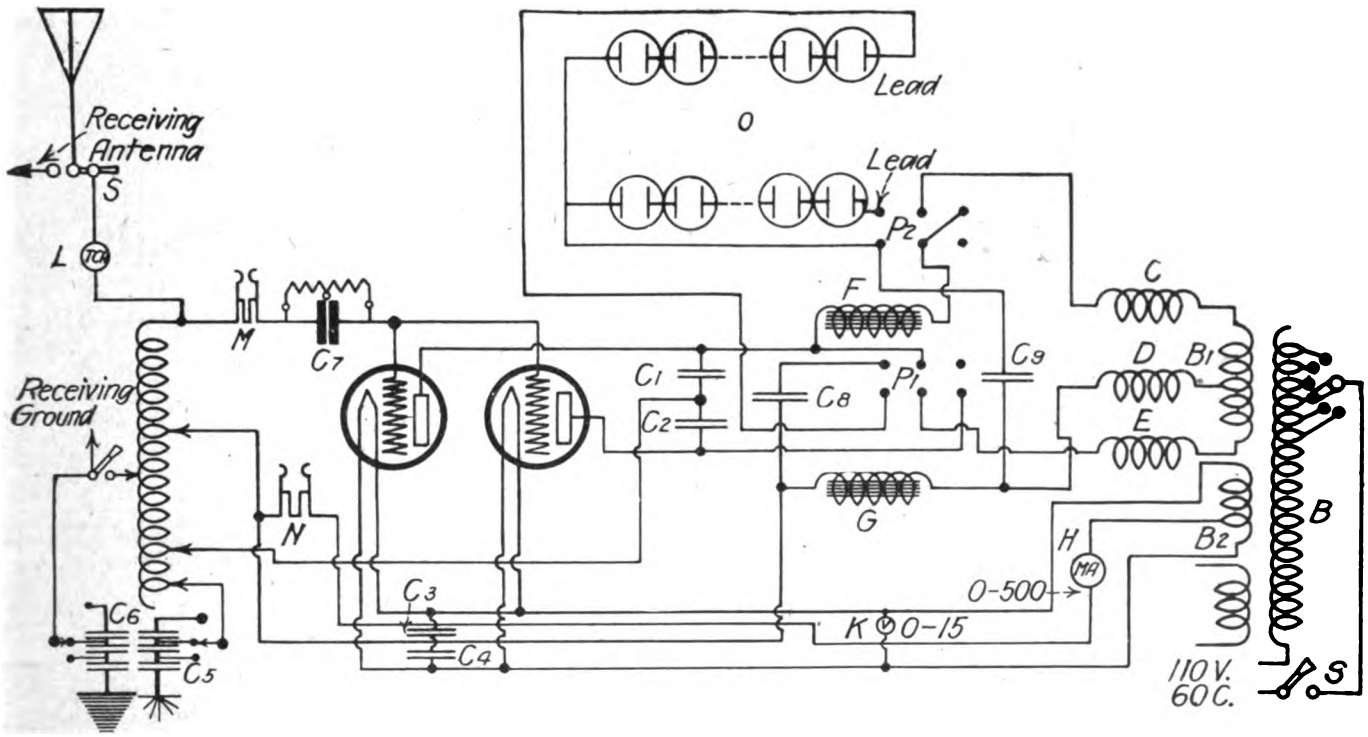
IN response to inquiries from many readers of RADIO WORLD, the hook-up of the transmitter devised by Paul Haus, radio amateur, whose call is 2VK, is published herewith.

As can be seen, the transmitter uses two tubes, getting the current for both the plate and filament through the agency of a combination transformer, which permits Mr. Haus to supply 12 volts for the filament and 1,500 volts to the plate, if he wishes to use that much. By the jack and plug arrangement, described in RADIO WORLD for April 7, 1923, it is permitted to use either a chopper or straight key. The jacks are shown in the diagram at M and N. The jack M is for either the chopper or a microphone, whichever is employed, but which Mr. Haus uses only for ICW with the chopper. The jack N is for the key, when it is necessary to use straight CW.

This transmitter is powerful and at the same time is not difficult either to construct or operate, and should prove a welcome answer to many readers who have written to us to describe a similar transmitter.

For those contemplating the building of such a set, a look at the carefully worked out cabinet and set, as shown in RADIO WORLD for April 7th, will give the prospective builder some ideas that he can very easily incorporate in his set, such as the method of mounting the tubes, the meters, and the easy throw-over switch from receiving to transmitting.

The hook-up published herewith is sufficiently plain and the caption describes the different parts,



C1 and C2, High Voltage Condensers of .002 Mfd.
C3 and C4, Bypass Condensers, .0005 Mfd.
C5 and C6, Series Condensers, .0003-4-5 Mfd.
C7, Grid Condenser, .0005 Mfd.
C8 and C9, Filter Condensers, 1 Mfd.
A, Tuner, 33 turns of No. 10 BSC wound on bakelite core, diameter 5 inches.
B, Transformer (C.W.), 750 Watts.
C-D-E, 200 D-L or Honeycomb Coils.
B1, High Voltage winding, 1,500 Volts each side of center.
B2, Filament Winding, 12 volts terminal.
F, G, Iron core choke coils of 1½ henries each.
H, Milliameter.
I, Grid Leak, 2,500 Ohms resistance.
K, Voltmeter 0-15 volts A.C.
L, Thermo-couple radiation ammeter, range up to 5 amperes.
M, Jack for chopper or microphone transformer.
N, Jack for key when CW is used.
O, Chemical rectifier, (Aluminum-Lead with borax solution), 48 jars in bank.
P1 and P2, Double throw switch (4 pole).
The tubes used in this set are U. V. 203, 50-watt.

The above references to the diagram make the Haus hook-up easy to understand.

A Novel Double-Control, Back-Panel Switch

By Arthur G. Shirt

THERE are a number of interesting features about the novel switch described and illustrated in this article which commend themselves to the amateur looking for the last word in switch construction. The switch is a double-control device, by which not only the number of turns on the primary of the variocoupler may be varied, but also the position those turns occupy on the tube of the primary. The advantage of the duo-control is immeasurable. Many amateurs would not be without it. Although mounted on

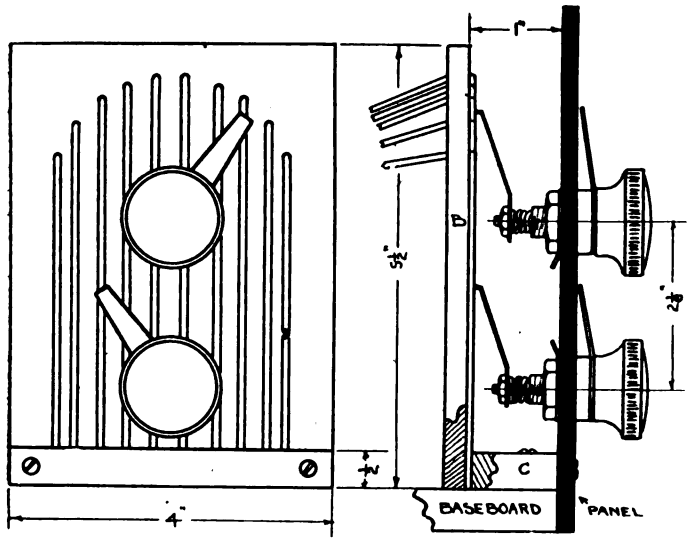

Fig. 1. At the right is shown how the wires are brought out from the coil to the sub-panel to serve in place of taps. At the left is shown how the switch arms are mounted, as well as how to mount the sub-panel.

the baseboard of the cabinet to the rear of the panel, this switch is operated from the face of the panel by two neat knobs, situated to the right or to the left of the dial which controls the rotor of the variocoupler. The switch is easily constructed, having been

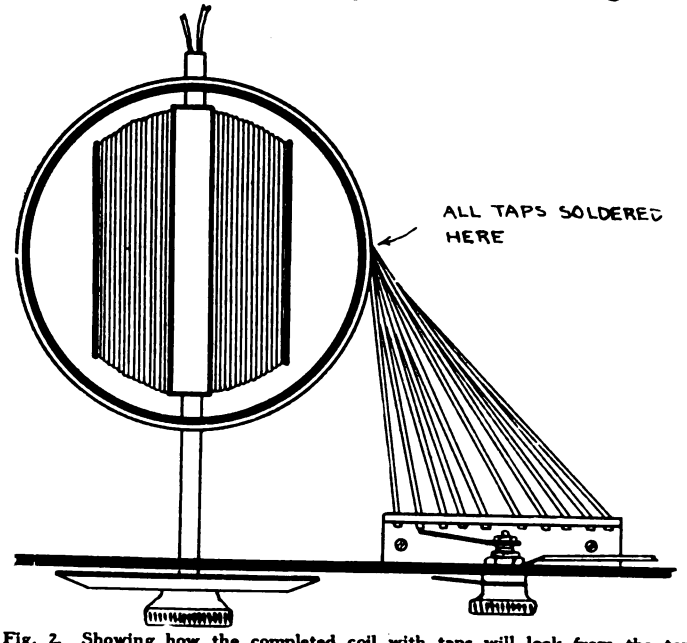

Fig. 2. Showing how the completed coil with taps will look from the top of the cabinet and giving a good idea of how to mount them on your panel.

designed so that its simplicity would appeal to those who cannot, or who haven't the chance to, do skilled work. There is no soldering in the building of the control itself, since the very leads which come from the taps of the primary coil are ingeniously made to serve as the switchpoints. When completed, this double-control switch is an instrument by itself, which may be moved from place to place in the cabinet without leaving a semicircle of unsightly holes in the panel.

The material needed—that is, for the particular size switch-arms shown in the illustrations—is a piece of hard rubber, composition, fibre, (or hard wood if these first three are not available) four inches wide, 5½ inches long and about ¼ inch thick. The same material of which the panel is made should serve admirably. This rectangular piece of material is the upright base for the switch. It is marked with the letter B in Fig. 1. A second piece of somewhat thicker material (about ½-inch) is cut one inch wide by four inches long. This serves the triple purpose of a space block between the front of the switch base and the back of the panel, of a means by which the switch base is held upright, and of a "clinch" strip which holds the contract wires in place. It is marked C in Fig. 1.

Two switch knobs, such as may be purchased as separate units, will be needed. You will find that most of them are designed along the lines of the ones shown

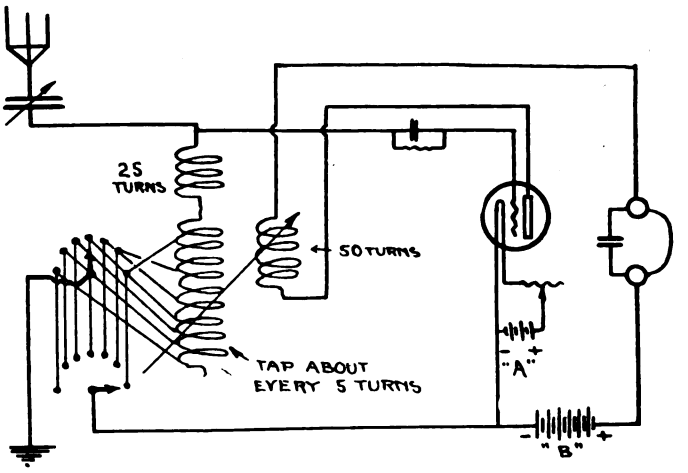

Fig. 3. A hook-up for the double control coupler. A WD-11 works admirably with this circuit, and by the use of the double control primary switch extremely sharp tuning is made possible.

with this article, so that the switch arm may be taken from its "front panel" position and shifted to a place in the rear. A pointer replaces the switch arm, and a semicircular scale is mounted suitably on the panel. With a switch arm about 1½ inches long, the distance between the centers of the two knobs should be 2½ inches or a trifle more. They are mounted in a vertical line, one above the other. This part of the construction is better done first than last, on account of the connection which goes to each switch arm.

The next step is to determine how many taps will come to the switch. The number decided upon should then be spaced off evenly on one edge of the bottom "clinch" strip, leaving a margin on each end of ½ inch. With a hacksaw, or a jackknife, groove each measurement on the edge of the strip so that there is a notch for each tap. Make the grooves no deeper than the thickness of the bare copper wire or the square bus bar material used as the switch leads. Drill two holes in the strip by which to bolt it to the upright base, and two others by which to screw it to the baseboard.

Now turn your attention to the rectangular switch base. Lay off a vertical center line up and down the piece. Measure down two inches from the top on this

How to Use a Two Element Vacuum Tube

By Harold B. Turner

EVERYONE who builds his own radio outfit desires to receive over a maximum distance with a minimum expenditure. The writer recently constructed a receiver which is far more sensitive than a crystal outfit and is more satisfactory and reliable in its operation. In fact, the writer's results have been so pleasing that he thought he would let his brother fans know how to do the same thing.

Nowadays everyone wants a vacuum tube set and yet everyone cannot afford to invest in the necessary storage battery, "B" battery and the other accessories that go to make up receivers of this type. While shopping around recently, I came across a new Fleming type vacuum tube which I purchased complete with all accessories for $2.50. This was a two-element tube operating from dry cells. The receiver circuit outlined in the diagram was set up and perfect reception was made possible. Previous to the purchase of this vacuum tube, I was using a crystal receiver. With the vacuum tube I was not only able to pick up stations that I had never heard before, but the quality of the reception was every bit as good as that obtainable with a good crystal set, and there was an entire absence of circuit noises and howling. In fact, one cannot make a two-element tube howl no matter how hard one tries.

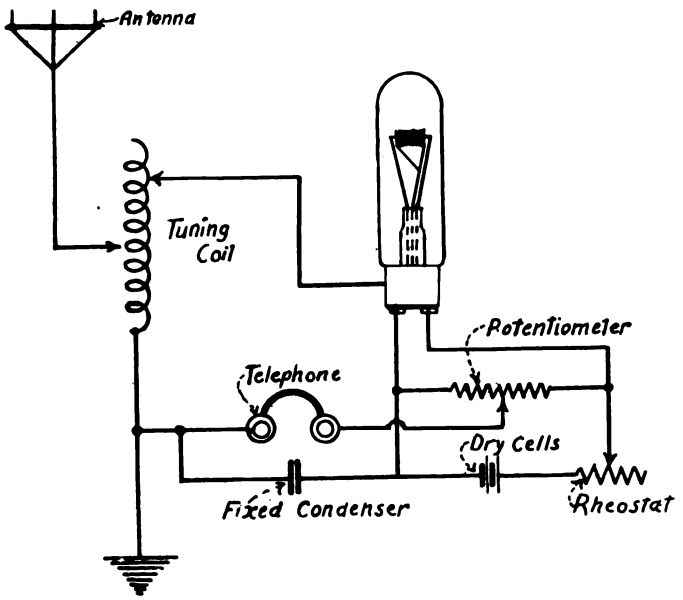

Fig. 1. Hook-up used by Mr. Turner with a Fleming type vacuum tube.

I have had such good results with this vacuum tube that one of my friends asked me to change his crystal set over into a vacuum tube set employing this same type of tube. I did not find it necessary to completely demolish his crystal set to make the necessary changes. In fact, I used all of the instruments of the old crystal set with the exception of the crystal.

The rheostat is carefully adjusted until the signals are loudest. When the rheostat was placed at the proper point, I did not find it necessary to adjust it further and tube retained its same degree of sensitivity for several hours. It is evident that it would not be advisable to operate these tubes without a rheostat as that would allow too much current to pass through the filament from the battery.

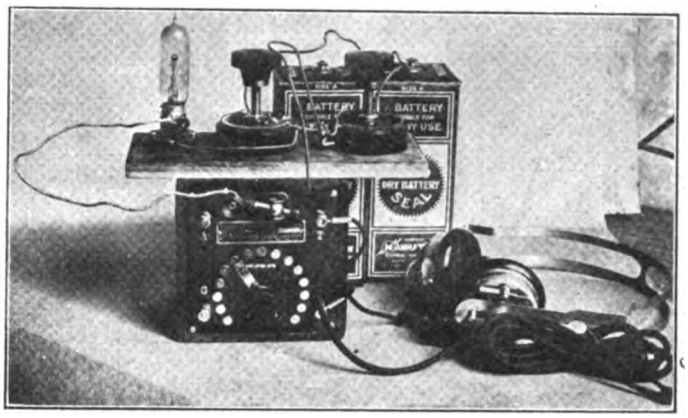

Fig. 2. Mr. Turner's two element vacuum tube set assembled.

The advantage of permanent adjustment of this arrangement will appeal strongly to those who have been troubled with crystal detectors. Crystal detectors are fine, but they do get out of adjustment and here is something that gives us just as good quality, greater distance and no trouble in adjustments.

In the way of experimenting I set up a second circuit, using a 200 ohm potentiometer. This allowed me to make the filament negative or positive. By the use of this arrangement the results were found to be a little bit better, but those who cannot afford the addition of the potentiometer can be assured that they will get good results well worth the trouble by using the other circuit.

(*Continued from preceding page*)

center line, and using the resulting point as a center, describe a circle on the switch base 1½ inches in diameter. Lay off at the bottom of the rectangular piece the same number of points as on the edge of the clinch strip, spaced the same way. Draw lines up from these points, and where the lines cross the upper half of the three-inch circle, there drill the holes for the insertion of the contact wires or bus bars.

It will be seen at this point in the explanation that the number of taps must be spaced off on the edge of the clinch strip within the compass of the particular sized arm on your switch knob. In the case illustrated, the compass is three inches.

When the holes are drilled the base is ready for the insertion of the leads. Preferably the leads should be of that silvered bus bar material which is sold for inside wiring on radio receivers. They may be of No. 7 or No. 9 bare copper wire, in case these bus bars are not obtainable. As many pieces are needed as there are taps on the coil. The proper length is from ten inches to one foot, according to how far away from the coil the switch is going to be located. For, as already mentioned, the same wire which serves as a switch contact goes directly to its particular turn on the variocoupler, where it is soldered at once to the tap. Fig. 2 illustrates this.

When you are selecting the drill for the holes, pick one that is slightly smaller than the wire or bar used. This difference in size will hold the wires in at the top of the switch base.

Now screw the completed instrument to the baseboard just behind the two switch arms, and the double control is finished. Before connecting it up take a glance at Fig. 3, which is a typical application of the double control switch, so as to make sure you grasp the principles on which the control works.

Radio Medical Service for Seamen Proves a Boon

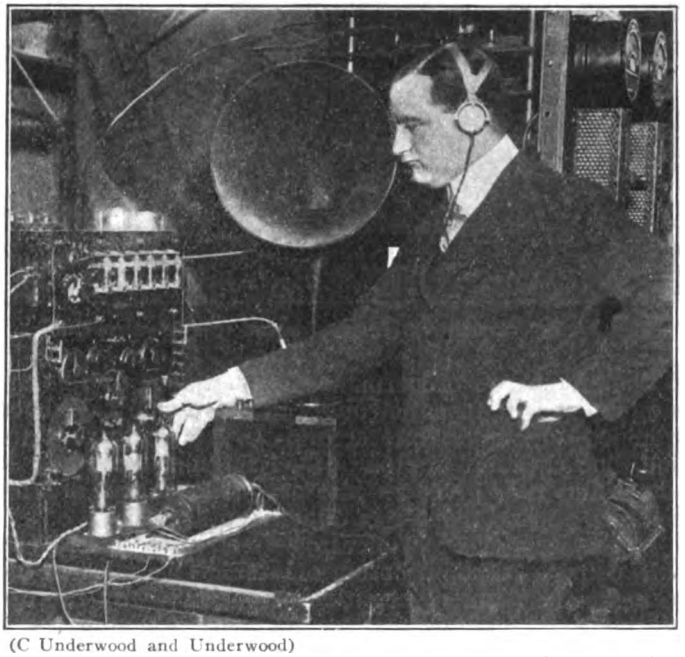
JUST a year ago the U. S. Public Health Service announced that it had completed arrangements to expand the medical aid service to American seamen, with which it had first been charged by Congress a century and a quarter ago, by prescribing by radio for any sailor who might be taken ill at sea and who might apply. Messages for aid were to be forwarded to the Service by the ship's radio via the Radio Corporation of America or the Independent Wireless Telegraph Company.

The range of diseases and mishaps for which aid has been invoked during the first year has been amazing. The list includes appendicitis, asthma, cramps, diarrhea, earache, eye injuries, heart disease, hernia, hiccoughs, influenza, infected teeth, malaria, opium poisoning, ptomaine poisoning and swallowing broken glass. Many of the diagnoses were made on board ship because sailors are resourceful in meeting emergencies. Sometimes interchange of several messages was necessary to obtain clear information as to the cause of the trouble. Cramps among the crew and later more cramps and worse cramps elicited the information that all the sick ate at a single mess. This known, treatment of the sick and means of preventing further cases were definitely outlined.

When the patient grows better and the captain's apprehension is relieved, the case usually drops from observation. Weeks afterward, perhaps, the interested hospital receives direct information as to what occurred later.

The "Ship's Medicine Chest" is a manual issued by the Public Health Service and carried by most ships.

Experimenting with Interference Preventers



(C Underwood and Underwood)

Professor Alfred W. Goldsmith, noted radio expert, and closely associated with numerous improvements that have been made recently, is here shown experimenting with apparatus which when completed, he hopes will eliminate all interference between transmitting stations to a degree that will be ideal. Professor Goldsmith is shown manipulating a receiver that incorporates several of his ideas, but that is at present not for publication. The receiver is the naval type which is much used now.

Public Health Information By Radio

THE end of the first year's existence of the Pioneer Health Information by Radio Service of the World, by which title the radio service of the United States Public Health Service is popularly known, finds it serving, in addition to NAA, Arlington, the Naval Radio Station, at Radio, Virginia, twenty-three co-operating broadcasting stations so situated as to serve practically every portion of the United States. Stations in Arizona, California, Colorado, Kansas, Massachusetts, Nebraska, Michigan, Minnesota, Missouri, Montana, Nebraska, North Dakota, South Dakota, New Mexico, New York, Ohio, Oregon, Pennsylvania, Texas, Utah, Washington, Wyoming and Ontario, Canada, are now co-operating with the Public Health Service in releasing its broadcasts by radio. Plans to extend the service to Alaska and Hawaii are under way.

The co-operating stations are operated by newspapers, universities, electrical supply companies and other commercial organizations. These broadcasts after being released by radio are, furthermore, regularly translated into seventeen different tongues by the Foreign Language Information Service and supplied to the foreign language press both in the United States and in Europe. Correspondence in regard to these broadcasts from as far away as Czecho-Slovakia has reached the Public Health Service.

In the first six months of its existence, directly and indirectly it is estimated that this service reached 27,000,000 people in the United States alone

Radio Equipment of the Navy Dirigible "ZR-1"

THE great Navy dirigible "ZR-1," now being completed at Lakehurst, N. J., with which flights to the polar regions are planned, will be as efficiently and completely equipped with radio as is possible. The following preliminary description of this equipment is from official sources:

The main radio set is located in the control car in a sound proof booth. For transmitting a Navy Type SE-1390 transmitter, using six 50-watt tubes and giving CW and ICW signals is used. This set can also be used in connection with the Type SE-1370 transmitter to give a power amplifier transmitting set for telephone work or CW and ICW signals to give steady wave lengths and signals despite any swinging of the antenna that may be caused by "bumpy" air. A reliable range of 400 miles is predicted for the transmitter.

A trailing antenna as at present employed by aircraft is to be used.

The power is supplied by a gas engine-driven generator and 24-volt battery, which drive a motor-generator.

Two receivers are provided, one the Type SE-1950 and 1805 detector and five-stage amplifier as used on F-5-L planes now. The second is a long wave receiver using a radio compass for the antenna. Due to the location of this compass and receiver away from the engines and propeller noises good results are predicted.

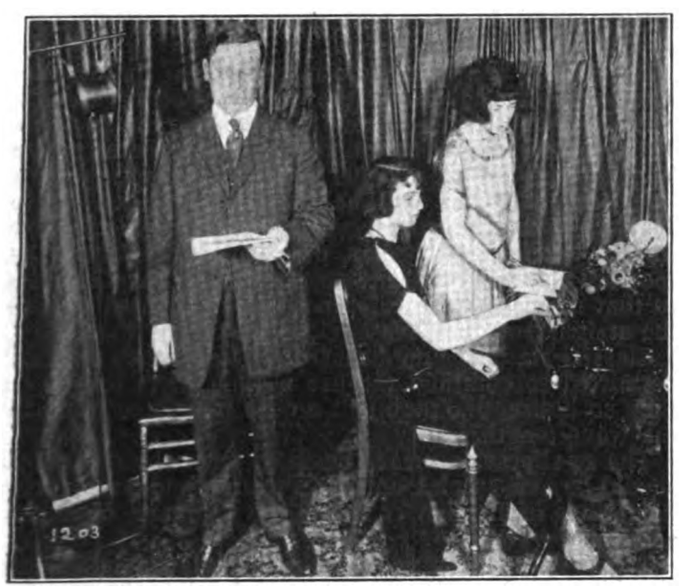
Install Radio in Every American College and School!

Radio World's Plan for Radio School and College Equipment Is Simple and Feasible

THE latent possibilities of radio as a practical, useful and well-nigh universal aid to education are but touched upon in a minor degree in the illustrations herewith depicting the first attempt at radio instruction in a New York City high school.

RADIO WORLD believes and prophesies that the

Radio In The Schools—Sending Instruction To a Distant Class



This picture shows H. W. Leyenberger, a teacher of the Haaren High School, New York City, giving via radio several problems for his class in mathematics to solve in their school room several miles away. Two girl students are checking the results of the problems. The broadcasting was done by Station WJZ at Newark, N. J.

day will come in the not distant future when every building in the great public school system of the United States will be equipped with a radio receiving set for the reception of instruction from central broadcasting stations.

In the larger cities, whose schools are, and will continue to be, crowded beyond capacity and where efficiency will demand every physical aid to instruction, it is not too much to expect that every class room will have its radio receiving set.

The country schools in isolated communities will probably be the first to adopt radio instruction. This will come about because thousands of farmers, whose children must depend upon such schools for their primary education, already are familiar with radio through their ownership of sets by means of which they have been receiving weather and crop reports, market prices and general news. They will not object to a slight increase in the local school tax because the extra money needed for radio equipment will be spent for something with which they are familiar—price and quality, both.

The increase in city school taxes necessary to provide sufficient radio equipment will, of course, be proportionately large, but as far as the individual taxpayer is concerned the added burden may be figured in mills.

Nearly all American universities and colleges can afford to purchase radio equipment—in fact, many of them already are supplied with at least one receiving set. Others can be added as occasion demands.

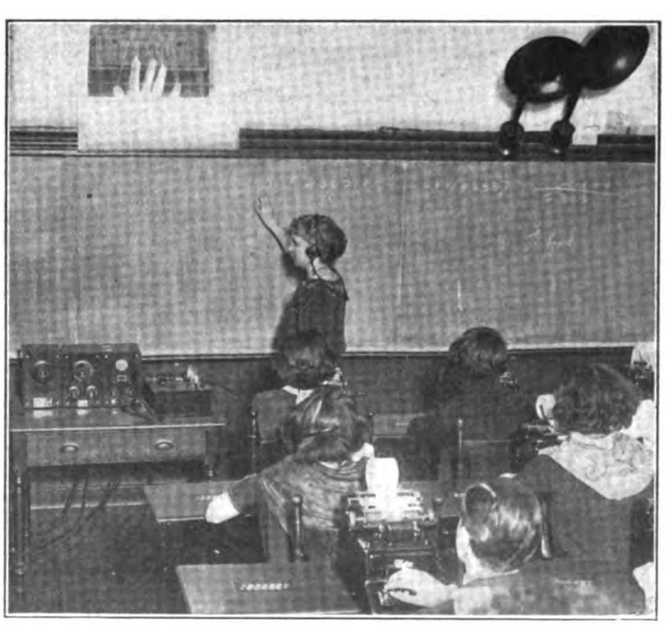
There is no doubt of the success of the idea. The experiment at Haaren High School, New York City, has proven the possibilities, even if that had been necessary.

RADIO WORLD is enthusiastic over the wonderful opportunity here presented to manufacturers and distributors of radio apparatus. An opening is offered such as comes to few young industries. Concerted effort and the consistent following of a well-formed educational plan by which Boards of Education throughout the country may be impelled to favorable action in this important matter are vitally necessary.

RADIO WORLD will assist the industry in every legitimate manner to accomplish the very desirable result of placing a radio set in every public school. If school principals, college presidents or technical instructors will write us their views, we will publish them. The illustrations herewith are almost self-explanatory. They show a class under instruction in adding machine operation, the instructor being located at a central point from which his words might as well be broadcast to a thousand receiving sets as to the one involved in the experiment.

From time to time RADIO WORLD will publish the views of eminent educators on this new phase of radio progress.

Radio In The Schools—Receiving Instruction In a Class Room



Miss Elinore Hastings, of the teaching staff of the Haaren High School, New York City, shown above instructing a class via radio. The questions are transmitted via radio from headquarters of the Board of Education, and the students of the class are then required to solve the problems. Station WJZ, Newark, N. J., is cooperating in these valuable experiments.

Hoover Approves New Wave Distribution—Much Interference Will be Eliminated by May 15

By Carl H. Butman

WASHINGTON, D. C.—Interference, the bugaboo of both radio operators and fans, will be greatly reduced, if not eliminated, by May 15th. On that date will go into effect the assignment of about 35 exclusive wave lengths to some 30 localities, where Class B, the high-powered broadcasting stations are situated. Wave lengths for Class A stations will also be assigned by districts by May 15, it is hoped.

Although Secretary Hoover is understood to have approved of the tentative allocation of the specific wave lengths to broadcasting stations, it is pointed out that each district radio inspector must now confer with the local operators and owners before the wave lengths are definitely assigned. For this reason the list is not yet made public.

All elements of the radio industry and public promised voluntary cooperation in an effort to eliminate interference especially in broadcasting, and officials of the Department of Commerce point out that it is now literally "up to them" to do so.

The tentative distribution of broadcasting waves is based on the recommendations of the Second National Radio Conference and is the first step in the application of the wave band allocations made recently. It will mean that anyone in the United States with a good receiving set will soon be able to pick up each and every high-powered radio broadcasting station and most of his local stations without experiencing the interference which has been prevalent for many months.

Practically every B station will have a national exclusive wave length, between 300 and 345 or 375 and 545, except where there are two or more in a locality, but the waves are assigned to localities rather than stations and will have to be shared in some cities. In four instances—New York, Philadelphia, Los Angeles and San Francisco—two or three additional wave lengths will also be assigned, but they will not be exclusive nationally. Those waves allocated on the Atlantic Coast will be repeated in the Pacific Coast cities. While not exclusive, these additional waves will aid in supplying additional facilities and will scarcely cause interference as the stations will be about 3,000 miles apart. The difference in time of three hours will also tend to eliminate any interferences. As soon as the nine radio inspectors can arrange with the Class B station owners in their districts, authority to broadcast will be issued on the specified wave lengths and stations will be required to use them only. Where two or more stations exist, a time schedule will be arranged. Until the assignments are made definitely, B stations will continue to operate on 400 meters, and C stations on 360, but by the middle of May it is hoped that all readjustments will be completed and the transfers made. A few radio wave lengths in each district have been reserved because of anticipated interference with other lines of communication or held for new stations.

By May 15 the nine radio inspectors of the department will also undertake the re-allocation of specific waves to old Class A or new Class C stations in their districts now operating on 360 meters. These wave lengths, between 222 and 300 meters, will not be exclusive nationally but will be exclusive in each radio district, giving practically every station a selective wave. Along the borders of adjacent districts, inspectors plan to arrange the allocation of wave lengths so that no material interference will be created due to the assignment of waves in close proximity.

Class C stations now licensed on 360 meters will be permitted to continue the use of this wave length if they so desire, but they will not be permitted to vary the wave length.

The re-allocation means much to fans, any of whom should be able to pick up any B station and any of the A stations in his district due to the allotment of many additional waves.

A great amount of additional work will fall upon the shoulders of the radio inspectors and unless the receiving public, operators and other interests co-operate by staying on wave lengths assigned, the work will be delayed and interferences will not be overcome.

High Speed Radio Transmission in the Army

SUCCESSFUL experiments in high speed radio transmission between Army Message Center and the Munitions Building at Washington, D. C., have just been completed. With new commercial apparatus capable of sending mechanically from a perforated tape up to a speed of 100 words a minute and recording the messages in a saw-toothed ink line on a tape, a reception speed of 65 words a minute has been achieved. After a little practice, Signal Corps experts say, their operators will be able mechanically to copy the received messages visually as well as by ear, and in this way a great saving of time will be made in clearing traffic.

The Signal Corps is planning to adopt high speed systems such as commercial companies are using in transatlantic work for transcontinental messages, and may order new mechanical radio equipment capable of operation at the rate of 200 words a minute. The practical value lies in the fact that when only a few clear hours a day are available, a great number of prepared high speed messages can be sent through in a short time. The transcribing on message blanks can be done after reception by several operators.

An addition to the Army radio net was made in March when the Fort Bragg, N. C., radio station WZG was put in operation. A new 5KW tube set has replaced the single tube set at Fort McPherson, Atlanta, which was not powerful enough to operate over the Appalachian Range. A new station with high powered tube transmitters will be completed at Fort Leavenworth, Kan., in August, and Fort Douglas, Utah, will also soon have new high-powered equipment.

High speed transmitting and receiving apparatus will also be installed between Washington, Fort Leavenworth, and Fort Douglas, and possibly at Fort Sam Houston, Tex. In good winter weather it is expected that Washington can clear traffic to Fort Douglas, Utah, but in the summer it will probably be necessary to relay through Fort Leavenworth, Kan.

The Signal Corps is now assigning waves lying within the bands recently allocated to the Government by Secretary Hoover's conference.

Coupling As It Affects a Transmitter

By W. S. Thompson, E.E.

IN a previous article the author pointed out very briefly the effect of coupling upon the selectivity of a receiving set and it is now his purpose to show by describing a few experiments how coupling will affect a transmitting set.

In order to give the reader a clearer idea of what the data obtained mean, the following description of the apparatus used is given:

As the object was to study the effects of coupling, a simple transmitting set, as shown in Fig. 1, was hooked up using a 100-volt 60-cycle alternator as a source of power. A quenched spark gap was used in order that damping of the primary circuit would be as

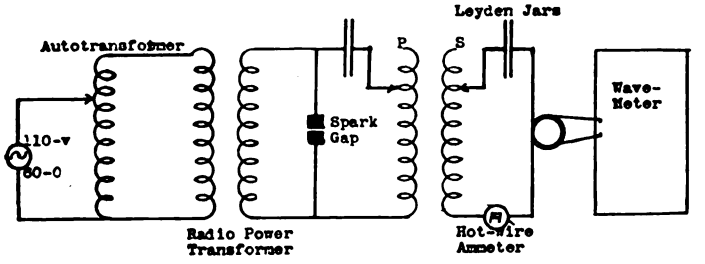

Fig. 1—Hook-up of apparatus used to obtain curves discussed in the accompanying article.

small as possible. The oscillation transformer was made so that the degree of coupling between the primary circuit and the equivalent antenna circuit was variable. The Leyden jars in the secondary circuit are the equivalent of an antenna, so that the circuit is identical with some in use today. In recording data for the curves reproduced, a hot-wire ammeter "A" and a wave-meter were used.

The wave length of the primary circuit was first obtained by using the wave-meter when the set was operated with the antenna circuit open, giving the true

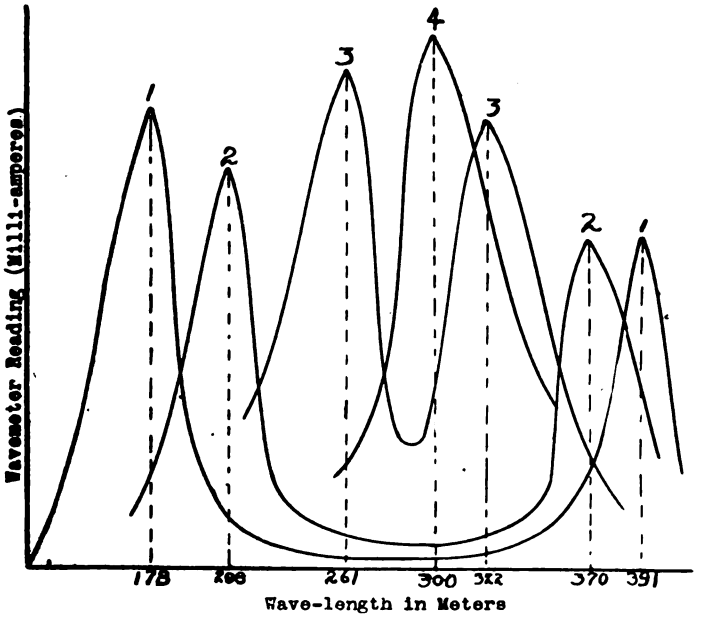

Fig. 2—Energy distribution curve of a transmitter for four degrees of coupling.

wave length of the transmitter. The antenna circuit was then tuned to the primary so that in taking all data, both circuits were tuned to the true wave length of the set.

The first part of this experiment was to obtain data for the energy distribution curves for four different sets of coupling. The purpose of the energy distribution curves are to show how much energy is being radiated from the antenna at different wave lengths. To get the data necessary, the wave-meter coil was coupled to a few turns of wire made in the secondary circuit. With the primary oscillating the wave-meter condenser was turned, taking a series of readings of the current induced in the wave-meter, and the wave length as shown by the condenser. This was repeated for four different settings of the coupling between the primary and secondary circuits.

Fig. 2 gives the energy distribution curves for the different settings of the coupling transformer as plotted from this data. In plotting these curves, distances along the horizontal axis represent different wave lengths to which the wave-meter was tuned and distances along the vertical axis represent readings of the wave-meter milli-ammeter.

Several very striking points are brought out by these curves. Both circuits of the transmitting set were

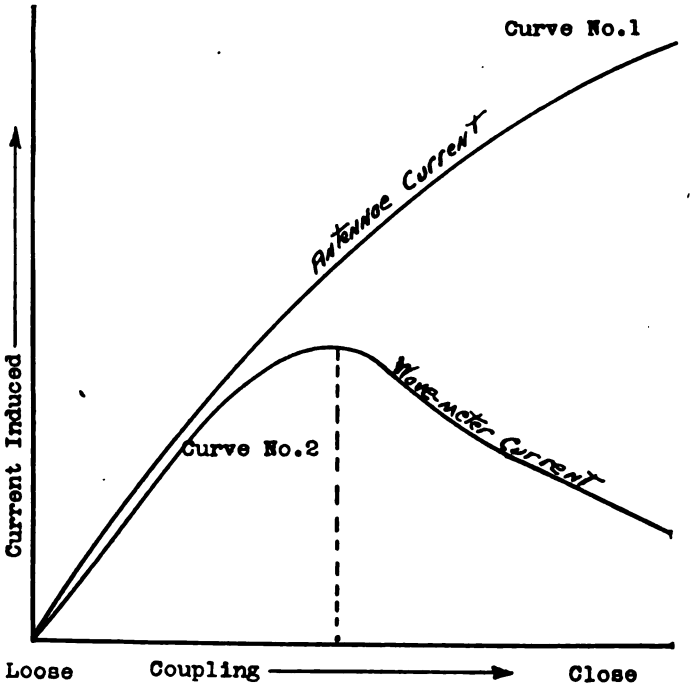

Fig. 3—Curves showing that maximum antenna current does not always mean maximum radiation on the true wave length.

tuned to 300 meters, as shown, but the set radiated maximum energy at 300 meters, only when the antenna circuit was very loosely coupled to the primary. Curves 1, 2 and 3, for which the coupling was close, all show that the antenna was radiating very little energy on 300 meters, but was radiating on two other wave lengths, one below and one above 300 meters. Also, the curves show that the energy radiated on the other wave lengths was less than that radiated on 300 meters when the coupling was loose.

To the amateur who is transmitting these curves ought to show that if he wants the maximum distance from his transmitter and wants a sharp wave, he should have his primary circuit coupled very loosely to his antenna circuit. Whenever a transmitting set is sending with a closely coupled transformer, it is invariably sending on two distinct wave lengths—one so high or

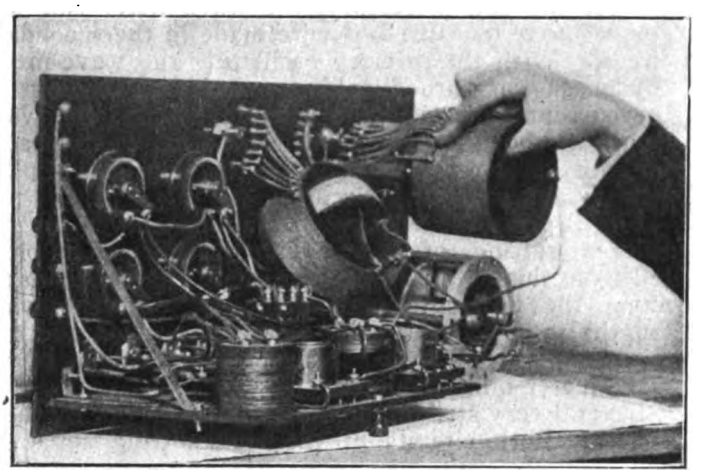
The War Department and the Farmer

THE Secretary of War delivered an address before the American Agricultural Editors' Association, at Washington, D. C., not long ago, of which the following is a partial report:

Rear View of the Kaufman Set



(C. Photonews, N. Y.)

Here is the original Kaufman circuit receiver. It marks somewhat of a departure from regular methods in more ways than one, but the most distinctive thing about it is the "active twenty" coil shown in the upper right of the picture.

In the present period of progress and transformation there is nothing more important for the people of the United States than to gain the frankest, most intimate contact with the departments of their own government. On the other hand, there is nothing which will more certainly produce the necessary support for the departments than to have their activities fully understood by the public. Our public must always rest socially, economically and politically, upon the solid foundation of the farm.

There is no class more vitally concerned than the agricultural with the welfare of our country as a whole—and there is no matter of greater present importance to our country than that of effectively building up our system of national defense. Our present work has, in many fields, continued earlier contacts, and the Departments of Agriculture, Interior, and War now find themselves in routine conference relative to some of the most urgent problems of agricultural development, such as those relating to water power and irrigation.

Because of the isolation of the farm the development of communication facilities is highly important, not only in transmitting weather reports, but also in broadcasting data on markets and in dispensing music and recreational programs to the living-room of the farmer. The prominent part played by the Signal Corps of the Army in building up our system of wired communication is being carried on fully as effectively in the promotion of radio. The Signal Corps is responsible for the use of the vacuum tube in this country, and also largely for the development of the small radio set now used so generally by the amateur. General Squier's recent invention will serve to bring the radio even more generally into the home of the farmer, with the resulting enrichment of agricultural life. In certain sections, such as the early frontiers and present-day Alaska, the farmer has had no communication with the outside world other than that afforded by the Army signal system. The radio web of the Army is today a reserve system that would enable our country to continue its general contacts even in the face of a complete breakdown of the civil lines. The modern farmer will appreciate what this means. He has learned to look upon communication as a primary need instead of as a luxury.

(Concluded from preceding page)

low that it often interferes with the broadcasting wave lengths. This is an explanation of why code is often picked up around 360 or 400 meters.

In order to show any reader who is sending that he is not always radiating the most energy when his hot-wire ammeter reads maximum, Fig. 3 is given. To get Curves 1 and 2 the coupling was set so that no energy was picked up by the antenna circuit. Then, as the coupling was made closer, readings were taken of the hot-wire ammeter "A" and the milli-ammeter in the wave-meter which was coupled to the antenna circuit. Curve 1 shows the way current, as indicated by the hot-wire ammeter "A," mounted as the coupling was tightened until it was maximum when the circuits were very closely coupled. But the readings of the wave-meter which showed how much energy was being radiated on the true wave length was not maximum when the coupling was very close. The maximum energy was being radiated when the coupling was loose, showing that the maximum reading of the hot-wire ammeter in an antenna circuit does not mean maximum radiation. The explanation of this lies in Fig. 2, which shows that with tight coupling energy is radiated on two wave lengths, neither of which gives a response that can be obtained when all the energy is on one wave length.

The author hopes that this explanation will make some of the readers who are sending, look over their transmitters to see if they are putting all the power of their sets into one wave length. This can very easily be done if a good wave meter can be procured. The following procedure will be found very satisfactory in obtaining maximum radiation on a given wave length. In order to make the explanation clearer, let it be assumed that a reader wishes to send on a 200-meter wave length. The first step will be to disconnect the ground and the antenna and couple the search coil of the wave-meter to the primary circuit. Then set the wave-meter condenser so that its wave length is 200 meters. Set the primary to oscillating and vary the number of turns on the primary inductance coil until the response in the wave-meter is maximum. This will be shown by a large reading of the milli-ammeter or by loudest response in the phones if the wave-meter has no current reading meter. Following this the antenna and ground should be connected and the secondary coupled very loosely to the primary and with the primary oscillating, vary the number of turns in the secondary until the hot-wire ammeter reads a maximum for that setting of the coupling.

The last and most important part of this adjustment is to make two or three turns in the antenna or ground wire as far away from the set as convenient and then to couple these few turns to the wave-meter still set at 200 meters. By changing the coupling between the antenna and the primary circuits, a point will be found where the response in the wave-meter will be maximum. This will be when the coupling is loose and the station owner may then be sure that the set, as it has been made, is giving maximum radiation on the given wave length.

Broadcasters, What Kind of Talent Do You Want?

Radio Fans, What Kind of Talent Do *You* Want?

Broadcasters, let us know the type of artist and the kind of material you prefer for your programs.

Radio fans, write and tell us the kind of program you like—whether instrumental, music, singing, comedy, recitations, service talks, etc., etc.

These replies will be published in an early issue of RADIO WORLD and the issue containing the wants and desires of broadcasters and radio fans will be specifically called to the attention of musical, vaudeville, dramatic and other talent in New York and throughout the country.

In this way the whole matter will be linked up so that everybody will know what everybody else requires in the important matter of broadcasting.

Broadcasters and fans, write us today and tell us what you want.

EDITOR, RADIO WORLD, 1493 Broadway, New York

See Next Week's Radio World

IS the radiophone industry about to be revolutionized?

Does the day approach when a radio receiver can be connected to an electric lighting fixture, as an electric fan is now attached?

RADIO WORLD will publish in its next issue a provocative article on a device which may be the entering wedge to radio possibilities now considered merely dreams.

Well Constructed Amateur Set Made by J. C. Gorman

(C. Photonews, N. Y.)

The radiophone station of J. C. Gorman, New York amateur, who has been heard a distance of 1,100 miles on phone and over 1,500 on CW. The transmitter is located on the left of the table, while the receiver is at the right. The receiver employs two steps of radio frequency and detector. Either one or two stages of audio-frequency can be used.

"Secret Radio" as an Aid to Naval Intelligence

DURING the recent cruise of the United States fleet for maneuvers off Panama, Secretary of the Navy Denby and members of the Congressional party with the fleet were intensely interested in an address by Captain Luke McNamee, chief of the Office of Naval Intelligence, on the subject of blunders in the World War due to misinformation supplied by intelligence agents.

Captain McNamee, who was stationed in London during the war on service in the War Planning Section, also dealt with some of the achievemtns of the British Navy as a result of accurate naval intelligence, and told of the early acquisition and dissemination of information which resulted in prompt measures by the British Navy in connection with the battle of Dogger Bank.

After a review of what had actually been done in the way of naval and military intelligence during the World War, Captain McNamee hinted at the possible use of "secret radio" in the next war—the sending of radio messages secretly in such manner that they might be picked up by the sender's own fleet, but remain a secret to the enemy.

"I am not speaking of what is desirable theoretically," said Captain McNamee, to the New York Times correspondent, "but of what was actually done in the World War, and we can be sure that all that is capable of vast improvement today. It may be that the one chief source of information, the radio, will in the next great war be entirely lost to us. Secret radio is well within the possibilities. The advantage of exclusive possession of such apparatus needs no comment.

"For combat information preceding and during a naval action the Commander-in-Chief will be largely at the mercy of his intelligence service. He may know in a general way the enemy's strength in the theatre of war and his possible intentions, but he will on the eve of action find the situation becoming hourly more confused by conflicting information—reports of enemy forces sighted by aircraft, by auxiliaries, by neutrals; false reports broadcast by the enemy, some of which will purport to come from his own ships.

"Amid all this confusion there must sit near the Admiral an intelligence staff that can winnow the wheat from the chaff. Expert radio men may know the wave lengths, the tune, the idiosyncracies and touch of the enemy's operators. This sounds impossible, yet it is the very thing that British operators did in the war. It was useless for the Germans to change call letters or exchange them between ships as long as the operators remained the same. They were spotted at once. The Oldenberg could not palm herself off as the Derflinger. The enemy's codes must be known, and, if not known, broken. Direction-finders will give the key to the probable source of dispatches.

"In the absence of aircraft a knowledge of the enemy's radio may enable direction-finders in the fleet to get an intersection on important vessels of the enemy main body that will at least give a clue to his location and course.

"In the German fleet certain ships were detailed to handle the traffic in groups. This facilitated the business of the fleet, but made it easier for the British intelligence service, who by listening only to the traffic ship, could catch all the messages of the group. The grouping for traffic also indicated what ships were together."

Westinghouse Cuts Out Broadcasting Copyrighted Music

RESPONDING to a demand of the American Society of Composers, Authors and Publishers relative to broadcasting copyrighted music, the Westinghouse Electric and Manufacturing Company announced last week that copyrighted music will no longer be sent out from its stations. The first step was taken when WJZ cut the opera, "Robin Hood," from its program.

In a statement the Westinghouse Company said that after a careful study of the subject it had decided to eliminate from its future programs all copyrighted music the copyright of which is owned or controlled by the American Society of Composers. Except for the elimination of certain copyrighted music, it will continue its broadcasting activities as heretofore.

How Broadcasters Can Beat the Music Publisher

THERE has been a lot of talk in recent weeks regarding the claims made by music publishers and various associations of authors and composers as to the very drastic attitude they intended to take regarding the broadcasting of their operatic, musical comedy or fugitive song numbers. They say they should be paid for the use of their material when broadcast just as they are paid by the phonograph companies.

Let us assume for a moment that we are running a broadcasting station. We receive nothing directly from this service. We do not want to be penalized for broadcasting songs and instrumental pieces which not so long ago the music publishers were dying to have everybody use, and in some cases paid handsome weekly or lump sums to vaudeville singers and other musicians for using. As broadcasters we know we are offering a great public service to radio and the public at large, and feel that the fees demanded should not be paid.

Supposing, however, that a fair argument does not bring the publishers to terms, what then can be done? The answer is simple. Every music publisher is obliged to boost his numbers so that singers will put them in their repertoire, phonograph companies will record them, and eventually the public will buy them.

Broadcasters can adopt practically the same method. Good song writers—and some of the most popular and successful in the business—can be engaged on a salary or royalty basis and if their output is released through all the other broadcasting stations there would soon be such a demand for these numbers that the music dealers throughout the country would be placing their orders for hundreds of thousands, and, in some cases, millions of copies. These new numbers could also be released through singers, orchestras, etc., and practically the same method of boosting procedure adopted as is now used by the biggest music publishers.

Broadcasters should not worry at all when it comes to a matter of getting up-to-date material. They can make their own. They can popularize it in a more expeditious and thorough way than was ever known in the old days of "song-plugging." All they have to do is to adopt the methods of their friendly enemy and go right into the song and instrumental sheet music business themselves in the manner indicated.

Who will be the first to put over this very practical plan?

Radio Penetrates Bank Vault

(C. International Newsreel)

Officials of the Stratford, Conn., Trust Company demonstrating that steel vaults, concrete casings and electric protective wiring are insufficient to keep radio waves from entering a vault. Under an official test, station WJZ at Newark, N. J., was clearly heard by the bank officials in the vault.

Germans Pay for Broadcasting

IN Germany radio fans, most of whom are bankers and business men, have to pay 500,000 marks annually for their radio broadcast service.

A financial and commercial news service has been arranged for broadcasting by the Express Service Company of Berlin, according to information reaching Washington. This private company, financed by Germans, has just secured partial use of the Koenigswusterhausen radio station from the Government for broadcasting international news received via Nauen from the United States, Switzerland, Sweden and other countries.

The news is rebroadcast over a radio phone circuit for about 800 subscribers, principally banks and industrial institutions, in about 200 cities. The company plans to handle New York quotations within ten minutes after their dispatch from this country and more rapidly, when possible.

Subscribers rent their receiving sets from the Express Company, paying an annual rental charge of 200,000 marks and an annual service charge of 300,000 marks. Two and a half hour schedules are maintained every morning and evening.

The Radio Primer

For Thousands of Beginners Who Are Coming Into Radio Circles

Weekly A B C of Radio Facts and Principles Fully and Clearly Explained

By Lynn Brooks

A LICENSE is necessary to operate a transmitter. What method should be pursued by the layman in order to obtain one?

A knowledge of the code is necessary. In order to learn the code, the simplest method is often the best. To do this, equip yourself with a buzzer, key and battery and practice sending dots, which is accomplished by holding the key down for a very short space of time. Practice this until the wrist is perfectly limber. In sending, the arm should not rest on the table, but be held a short distance above, and the key manipulated by moving the hand and wrist in an up and down motion. When dots can be sent quickly and evenly practice sending dashes, which are three times as long as a dot. Then with the code in front of you, practice sending the letter "A," which is a dot and a dash. Practice until it can be sent easily and distinguishably. Then go to "B," which is a dash and three dots. Do this with the entire code until each letter of the alphabet can easily be sent. Then try to work individual letters, picked up at random. When your wrist is limbered up and will respond easily, go through the code and memorize it in the same way, by sending the entire code, each letter once or twice. If an error is made in a letter, stop and practice the particular letter until it is perfect. Don't try to speed up, but send easily and slowly, making each letter perfect. Speed will come later, with greater familiarity with the code itself.

* * *

What are the "Q" signals?

The Q signals are a list of abbreviations, adopted by the International Radio Convention, at Geneva, Switzerland, to enable transmitting stations to give information and ask questions with the least amount of time and energy. They are three-letter codes which, if a query is sent after them, mean the question; whereas, if they are sent without the query, the answer to the question is meant.

* * *

Is any extended technical knowledge required in order to obtain a license?

The technical requirements necessary are a thorough knowledge of the type of receiver you are using and a schematic diagram for it. A knowledge of the transmitter that is to be used, such as the power required, out-put of transmitter, the name of the parts, their purpose in the set, the wave length of the antenna used, and a diagram of it are also necessary.

* * *

Into what classes are licenses divided?

Radio licenses are divided into two classes—amateur and commercial. The amateur class is again divided into first, second and third class. The operating license is then sub-divided into first, second and third grade, dependent upon the speed of reception and transmission of signals. The commercial operator's license is divided in the same manner.

* * *

Can a license be obtained when a person is not able to go to the custom house in person?

In case a person desires a license, yet is so situated that he cannot conveniently take a personal examination because of living at a distance from one of the naval stations or custom houses, he is at liberty to write to the nearest one, requesting the papers. By filling them out and swearing to them before a local notary, as to his operation of a transmitter, and the answers to the questions, he will be allowed the privilege of a license if the papers are satisfactorily filled out.

* * *

When a storage cell has been left standing for any length of time, what should be done before it is returned to use?

In case a storage cell has been left any appreciable length of time without charging the following action should be taken if the cell is to be saved: The electrolyte should be poured out, the cell filled with clean distilled water and placed on charge. Then the cell should be discharged for a short time and the distilled water removed. Clean new electrolyte should now be placed in the cell. Then the normal charge is put on and the cell slightly overcharged. Examine the bottom of the electrolyte by means of a glass tube in the following manner: Take a clean glass tube, open at both ends, and of sufficient diameter to insert in the end of the cell. Lower it carefully to the bottom of the cell and close the top by putting the finger over it. If when the tube is taken out the sample of the electrolyte withdrawn in the tube is muddy and filled with slime, the whole cell should be thoroughly cleaned.

Voice Amplifier Directs Passengers to Boston Elevated Cars

(C. Western Electric Co.)

Mayor James Curley, of Boston, using the microphone of the Western Electric public address system to amplify announcements on the Boston Elevated Railway at Park Street Station.

Radio and the Woman

By Crystal D. Tector

FRIEND HUSBAND and I went over to the new radio apartments in Newark, N. J., the other evening just for a lark, to see if it was fun having anybody else tune in stations for you while you listen. I think it is a good idea, and if we ever decide to move to the city (F. H. decides that every time he has to mow the lawn) I shall insist that we move into an apartment that at least has antennae equipment installed for every apartment. As it is now, the operator in the Newark apartment has to be a diplomat, there are so many different programs going on. It really is hard to tune in the right one. Even if you do like jazz, you have to consider that the people downstairs may like to listen to the lecture on "Elephoyn Eucalyptus—Its Origin and Habitat," and he certainly must exercise care. I think that if I were an operator I would make a canvass of the families and find out how many liked opera and how many liked jazz, and then I could divide the program to suit every body, even the little flappers and their visiting flippers.

* * *

Convincing proof of the value of broadcast religious services was received by WGY, the Schenectady broadcasting station of the General Electric Company from a blind woman living in East Orleans, Mass., near Cape Cod. The paper was creased under each line of writing and it was evident that the creased line was used by the writer to guide her pencil as she wrote the following appreciation: "I am writing you a few lines this beautiful morning to tell you how much I enjoyed your good sermon Sunday afternoon, also the singing of 'Just as I Am,' and others. I heard every word of the sermon and singing, which was fine. I could hear just as plain as though you were in the room.

"What a wonderful invention! A friend and kind neighbor took me to his house to hear the radio. I am an old woman, almost 75 years old. Have been stone blind over twelve years, have not seen one ray of light. I take care of a crippled husband who is over 80; cannot walk a step alone. I dress and undress him every day and wait on him. Sometimes the way seems dark, but my dear Heavenly Father gives me strength every day, and at night I say I am a day nearer home. I go to church or Sunday School and do enjoy it so much. I gave myself into God's hands over 50 years ago and He has never failed me yet. I always trust Him. He knows what is best for me. Pardon me for writing, but I did want to thank you for that service. May God bless you, is the prayer of your friend.

"P. S.—It is one of the most wonderful of all inventions to know that I can sit here in an easy chair way down on old Cape Cod and hear such lovely sermons and singing. God bless the man that invented it. I hope to hear you again some time."

* * *

'Member some time ago, I told everybody about my little friend up in the North Woods who appreciated radio so much? Well, I just received a letter, telling us that her father had "taken on" as a guide to a party of hunters who were spending the spring up there, and had brought along little receiving sets which could be carried by each man, and that they installed a small transmitter "right in our cabin" and that the man left in charge taught her the code. She says: "When the party broke up, you can imagine our surprise when the host of the party told them to leave the transmitter there and also one of the small receivers, so that I could keep in touch with daddy. Well, I am going to write for a license right away, so that I can use it." Now there is a novel idea for you Nimrods when you go camping this summer. Take along your receivers and make up small low power battery operated transmitters, and you'll never get lost.

Answers to Readers of Radio World

I CONSTRUCTED the Flewelling described in RADIO WORLD *for February 24, and, while it worked fine on local stations, it does not bring in the DX stations as clear and loud as I would like. I am using the following apparatus: Freshman grid leaks and condensers, Bradleystat and honeycomb coils. The set whistles very loud when I try to bring them in. A WD-11 is used, with 67½ volts on the plate. Would a WD-11 function with a single-circuit receiver using the same apparatus?—Harry E. Halldeman, care of Keystone Fruit Co., Cincinnati, Ohio.*

We would advise the following: If possible use a 201 U. V. with this set, as it has been found that it will function better than the WD-11 because of the increased plate surface and greater spacing between the elements. In order to decrease the whistle (it cannot be entirely eliminated without seriously impairing the circuit's work) you will have to vary your grid leak, both in the grid circuit and also in the filament condenser bank. This whistle can be brought to such a high pitch that it is almost indistinguishable to the human ear, and at that point it is very weak. Incidentally, this is the point at which the circuit works best, and the distant stations will pound in. The apparatus you are using can be employed for a single-circuit set, using the 50 as the tickler and the 75 as the primary coil.

* * *

I constructed the improved WD-11 receiver illustrated by C. White, using the apparatus mentioned, and get local work very fine, but with a lot of whistling and hissing. I have the rotor of the condenser C1 connected to aerial and stator to the grid. The condenser C2 has the rotor connected to grid and stator to the plate lead. Is this correct? Will it be practical to use one or two steps of A. F. amplification with this or any standard hook-up?—C. J. Wehmayer, 394 Penrose Street, St. Louis, Mo.

The condenser C1 should be connected between the antenna and the beginning of the first or primary coil of the tuner. The second condenser should be connected across the near ends of both coils. It should not make much difference in a single circuit which side of the condenser is connected. Would advise the use of a potentiometer in the filament-plate battery lead. Try connecting the grid leak between the gride side of the condenser to the minus side of the filament circuit. Try increasing the capacity of the grid condenser by placing another fixed (small size—.00025 mfd.) condenser in parallel with the grid condenser you are now using. If you desire to increase the strength of the received signals it is perfectly advisable to incorporate one or two steps of audio-frequency amplification. Audio-frequency, as you probably understand, will only allow you to amplify signals that you can receive on detector alone.

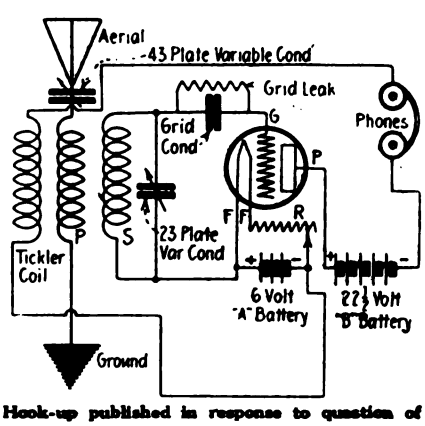
* * *

Kindly give me instructions for the construction of the transformers used in the Haseltine neutrodyne receivers. What is the capacity of the neutralizing condensers used? Where can blueprints for the construction of such a set be obtained? Can ordinary radio-frequency transformers be used in this circuit? What is the range of such a receiver, and what plate voltage should be used?—Emil R. Entress, 83 Main Street, Hackensack, N. J.; F. E. Roberts, Fountain and Dean Streets, Providence, R. I.; J. Scouten, Fall River, Mass.; C. R. Mason, P. O., General Delivery, Liberty, N. Y.; F. S. Meyer, St. Louis, Mo.; R. L. Alexander, Pawtucket, R. I.; J. K. Hines, San Antonio, Texas.

To these, and many other anxious readers, RADIO WORLD wishes to state that all the information that can be obtained was printed in our article on the Hazeltine neutrodyne circuit receiver in RADIO WORLD for March 31. This is a patented circuit, and such details as the construction of the radio-frequency transformers and the neutralizing capacities cannot be published at the present time.

* * *

Kindly publish a hook-up using the following apparatus: Three honeycomb coils, detector, bulb, phones, batteries and necessary condensers.—M. L. Ronecto, 113 Vine Street, Pittsburgh, Pa.



Hook-up published in response to question of M. L. Ronecto. The different parts are all properly marked.

The hook-up you desire is published herewith.

* * *

Where can pictures and blueprints of the Lighthouse receiver be obtained?—J. Thurriault, 20 Broadway, Cohoes, N. Y.

Write to C. W. Tupper, Bureau of Lighthouses, Washington, D. C., and you will be advised of their cost. They will be sent to you on receipt of the price.

* * *

Have constructed the Sorenson hook-up as described in RADIO WORLD *for January 20, but I cannot get any oscillation or regeneration. I have checked the hook-up over thoroughly, but cannot find what is wrong.—C. C. Huntington, Mauch Chunk, Pa.*

Reverse the connections on your 75-turn tickler coil. Use a small fixed condenser across the B and phone leads. Connect the B lead to the opposite side of the filament circuit from that shown in the circuit.

* * *

In RADIO WORLD *for November 25, 1922, you published a circuit by J. Schuck. What is the size of wire and number of turns used on each side of the rotor? What is the size of wire and number of turns on each side of the stator? What is the inside diameter of the stator and clearance of stator and rotor?—C. C. Powers, 403 West 33d Street, Richmond, Va.*

In regard to this hook-up it may be said that any manufactured variometer will work satisfactorily and does not have to be made. However, for your own information 20 turns of No. 18 or 20 wire on each side of the rotor will do. About 16 to 18 turns of the same size wire on the stator is O. K. Variometers are generally made with a 2½ or 3 inch rotor; therefore the stator diameter will be about 3½ or 3¾ inches to work satisfactorily, although this will be a little close.

* * *

Can I use a U. V. detector tube in the Flewelling circuit? Can spider-web coils be used with this set instead of the honeycomb coils?—Oliver Carmer, 1517 Franklin Avenue, Fort Wayne, Ind.

The tube you mention is perfectly O. K., and you can also incorporate spider-web coils in this circuit.

* * *

Should grid leaks be used in the hook-ups published in RADIO WORLD *for March 10 on page 20, and what is the capacity of the condenser used?—R. W. Kirkpatrick, Anderson, S. C.*

These hook-ups will work without grid leaks but it will improve the selectivity if a grid leak is used on the last one. The variable condenser should be .001.

* * *

Where can I obtain a hook-up embodying the following: One step of radio-frequency, detector and one of audio, with the regular three-circuit regenerative receiver?—J. K. Eisenberg, Jauney & Co., 133 So. Fourth Street, Philadelphia, Pa.

We refer you to the diagram published on page 19 of RADIO WORLD for February 24, where you will find what you desire.

* * *

Kindly publish wiring diagram of two step amplifier for the long wave receiver published in RADIO WORLD *for June 24, 1922, utilizing the new 201 A amplifier tubes. —Henry Zube, 1311 16th Street, Lorain, Ohio.*

If you will refer to page 26 of RADIO WORLD for March 31, 1923, you will find the hook-up you desire. The grid leak can be omitted for the receiver you mention.

* * *

What is the U. V. 201A tube? What plate voltage is used on it? What is the price, and where can it be obtained?—A. J. Howe, R. F. D. 7, Mason, Mich.

We refer you to RADIO WORLD for March 24, 1923, where you will find a complete description of this new tube in an article by J. L. Bernard on page 8. This tube is obtainable in any up-to-date radio supply house. The list price is $6.50.

* * *

Am enclosing a sketch of my receiver, and wish some advice on same. When I tune in a station I have much trouble, because my circuit oscillates so violently that the voice is all muffled. I am using the best apparatus obtainable, and only use 22 volts on the plate. Would the set work without the variometer in the plate circuit? —L. L. Hamilton, Topsham, Me.

Put a potentiometer in the filament circuit of the first tube. Allow more space between the two variometers and the vario-coupler. You have them too crowded. Try bridging the grid leak between the grid side of the condenser and the negative side of the filament circuit. This might help. The set would work without this variometer, but it would make it harder to obtain regeneration without it.

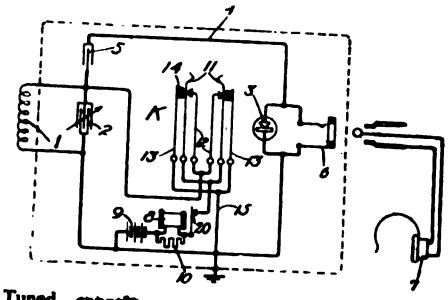
Latest Radio Patents

Wave Meter and Similar Electrical Devices

No. 1,448,579: Patented March 13, 1923. Patentee: George H. Stevenson, Rye, N. Y.

THE invention relates to wave meters and similar electrical apparatus, and more particularly, to means whereby the frequency calibration of such apparatus will not be rendered incorrect by the opening or closing of a key connected to the circuits of the apparatus.

It is customary in the arts dealing with high-frequency currents when wave lengths are to be measured or compared, to make use of a wave meter which for some purposes consists of a simple tuned receiver and detector for high-frequency waves and for other purposes consists of a low power generator. The usual manner of changing the apparatus to form a local generator is to include in circuit a buzzer or self-interrupting electromagnet which causes the tuned circuit of the wave meter to be excitd at its resonant frequency. It has been found that the key which serves to connect the buzzer into the circuit has a capacity between its contact blades of sufficient magnitude to cause the wave length calibration which is correct with the key opened to be incorrect when the key is closed or vice versa. This happens because the effective capacity of the key blades is in shunt with the tuning condenser of the tuned circuit when the key is opened. This capacity, in a particular instance, is of the order of 10×10^{-13} farads. A capacity of this magnitude produces appreciable effects at radio frequencies. By placing additional insulated blades on the key and connecting these additional blades in circuit so that when the key is closed their capacity will be substituted for the effective capacity introduced by the contact blades when the key is opened, the calibration may be made correct for either operative condition of the apparatus.

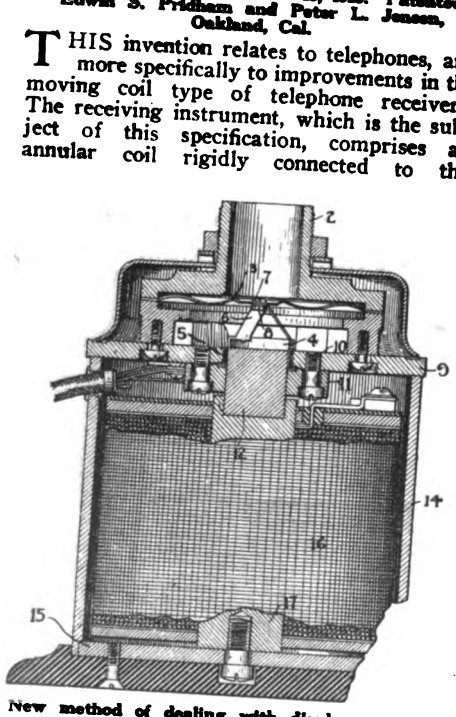


Tuned capacity wave meter, making more accurate readings possible.

Electrodynamic Receiver

No. 1,448,279: Patented March 13, 1923. Patentees: Edwin S. Pridham and Peter L. Jensen, Oakland, Cal.

THIS invention relates to telephones, and more specifically to improvements in the moving coil type of telephone receivers. The receiving instrument, which is the subject of this specification, comprises an annular coil rigidly connected to the diaphragm. This coil is disposed, so as to be freely movable, in a strong concentric magnetic field, produced either by a permanent or an electromagnet. The magnetic field is so arranged that the lines of force cut the annular coil at all points in the same direction. This is accomplished by having one of the poles of the magnet within the coil and the other completely surrounding it.



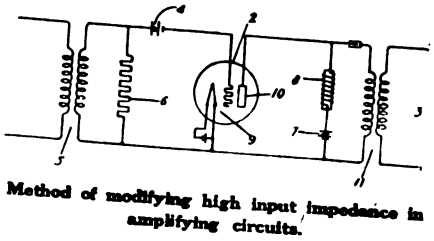
New method of dealing with diaphragm and electromagnets in telephones and loud speakers.

Thermionic Amplifier Circuits

No. 1,448,550: Patented March 13, 1923. Patentee: Harold D. Arnold, Maplewood, N. J.

THE invention relates to repeater circuits wherein an electron-discharge device is employed for receiving comparatively weak incoming impulses and for transmitting them in the same form or in a modified form, but with amplified energy. Such an amplifier, which has a cathode, an anode and a control member, usually in the form of a grid electrode, has a very high impedance between control member and cathode, which are the usual input electrodes. This impedance is of the order of 25,000 ohms or more, being in the nature of a space discharge path between electrodes in a vacuum. Preferably, the vacuum is as perfect as practicable, substantially no positive ionization taking place during the operation of the device. In case a source of potential is employed for making the potential of the grid always negative, the input circuit impedance is of the order of infinity, for no electrons can flow from the filament to an electrode which is negative, so that no current flow takes place between cathode and grid, even though the latter does respond to the incoming potential variations.

An object of the present invention is to modify the effect of this high input impedance so that it may have any desired finite value.



Method of modifying high input impedance in amplifying circuits.

Signaling System

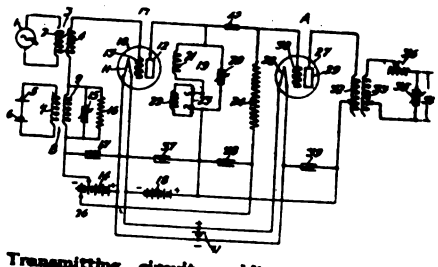
No. 1,448,216: Patented March 13, 1923. Patentee: Raymond A. Heising, Millburn, N. J.

THIS invention relates to signaling systems, and more particularly to signaling systems of the type in which high-frequency oscillations are modulated in accordance with signals.

An object of the invention is to provide a modulating and amplifying arrangement of the vacuum tube type in which the number of necessary current sources may be small.

Another object of the invention is to provide means to enable vacuum tubes arranged in cascade to be supplied from common sources of electrical energy.

A further object of the invention is to provide a circuit connection for a vacuum tube modulator and vacuum tube amplifier which will permit the use of common sources of energy for filament heating, space current and impedance controlling purposes.



Transmitting circuit enabling a number of tubes to be arranged in cascade.

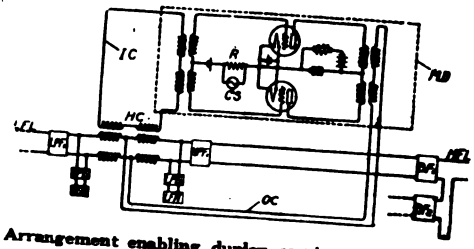
Still other features of the invention relate to certain combinations and arrangements of circuits hereinafter described and particularly pointed out in the claims, the advantages of which will be apparent to those skilled in the art.

* * *

Duplex Carrier Wave System

No. 1,448,488: Patented March 13, 1923. Patentee: Jacob S. Jammer, New York City

THIS invention relates in general to duplex transmission or signaling systems, and more particularly to carrier current telephone systems. The principles of the invention are more particularly adapted for application in systems employing conductive circuits throughout, but may be applied in systems in which the high frequency transmission is carried on through the natural media.



Arrangement enabling duplex carrier wave transmission.

An object of the invention is to provide systems of the type wherein a single apparatus is used to modulate waves passing in one direction and to detect waves passing in the other direction with improved line balancing impedance means. Individual means are provided for balancing the high frequency line separately for each carrier frequency. Since, with carrier currents of the frequencies ordinarily used, a high frequency line often varies considerably and irregularly in impedance for the various frequencies it is of considerable advantage to balance the line separately.

A further object is to provide means in connection with the modulator-detector for compensating for the attenuation produced in the circuit by the various apparatus.

The WD-11 Vacuum Tube

By G. Y. Allen

Radio Engineer, Westinghouse Electric & Mfg. Co.

CONSIDERABLE misinformation has been circulated from time to time on radio apparatus, its construction, use and application. This is particularly true in the case of the WD-11 vacuum tube, the most popular tube on the market today, possessing characteristics attractive to the average user, as it permits the use of a radio set in places remote from storage battery charging facilities such as the isolated farm, the seashore, the summer camp, the small yacht and other places too numerous to mention.

Let it be said in all fairness that the WD-11 vacuum tube was not the first vacuum tube designed for dry battery operation. It remained for the Westinghouse company to improve the mechanical features of the dry battery tube and to make it a commercial success. * * * *

In constructing the WD-11 tube, the tungsten filament is replaced by a platinum filament coated with certain salts that will allow greater electron emission with less battery capacity. This insures a good amplifying tube with very little energy expended in heating the filament. This development has made possible a tube having all of the desirable properties of an untreated tungsten filament tube and which can be operated from the power supplied from a common dry battery.

Although the principle upon which this tube is designed has been known for some time, it remained for Westinghouse engineers to develop it commercially so that it would be sufficiently rugged to give even a longer life than was experienced with 6 volt tubes. Through processes that have been developed recently, the WD-11 tube has been perfected to the point where, if not mistreated, its life is in the neighborhood of 1,000 hours.

The WD-11 tube is an excellent detector and when used in this capacity operates to best advantage at 22½ volts applied to the plate. Although values of grid condenser and grid leak are not at all critical, good average values are 2 meghoms resistance for the grid leak and 250 micro mfds. for the grid condenser. Let it be said here that all WD-11 tubes are exhausted to an extremely high vacuum and they do not depend upon enclosed gas for their detecting properties. They are thus not critical in any adjustment either to filament current, plate voltage, or to the constants of the circuit in which they are used.

When used as an amplifier, the WD-11 tube may be supplied with plate voltages varying from 45 to 80 volts. Voltages upward to 200 volts may be used with corresponding increase in volume without [illegible]e to the tube. When using high [illegible]s on the tube there appears at [illegible]ithin the cylindrical plate a blue glow [illegible]at is sometimes mistaken by the uninformed as an indication of ionized gas such as would occur in a tube that has leaked or such as would be noted in a soft tube. This glow, however, in no way interferes with the operation of the tube and is thought to be caused by phosphorescence given off by the salts that are used to coat the filament. * * * * *

The WD-11 tube is designed for operation from a single cell of 1½ volts standard dry battery. When more than one tube is used in parallel an additional standard battery should be used for each additional tube, all dry batteries being connected in parallel. Care should be used to see that dry batteries so connected are all fresh, and old batteries should never be connected in parallel with new batteries. A fresh dry battery will operate a WD-11 tube intermittently from 60 to 90 hours, depending upon the length of intervals the tube is used. Of course, the battery current should always be turned off except when the tube is actually being operated. * * *

Quite recently the public press has elected to criticise the manufacturer of this tube, suggesting that the supply was being purposely curtailed to insure price maintenance and other improper factors.

As many will remember, the radio season last fall was a month or six weeks later in the year than would normally be expected as very warm weather persisted until well into December, with the result that the radio set in the home was not as well patronized as might reasonably be expected, for the reason that people found it convenient and entertaining to participate in diversions outside of the home.

With the coming of the colder and more inclement weather about the first of January, radio again became a convenient and attractive form of entertainment for the average family, with the result that a great demand was created for radio apparatus.

The manufacturer's stock of WD-11 tubes at the beginning of the radio season was in excess of 100,000, which was considered adequate in the light of previous demand to relieve all excessive demands for a period of several months, but, coincidnt with the opening of the radio season, the public largely by discovery that WD-11 tubes would function satisfactorily in all forms of radio appliances, almost overnight recognized the very superior merits of this tube, with the result that the substantial stock and, in addition, the daily output of the factory was rapidly absorbed despite the fact that production facilities have been crowded to the utmost and five or six times as many tubes are being made per day now as were made prior to January 1. The demand is still in excess of the supply, but the manufacturers express great hope that everyone will be provided with these very desirable tubes within the next thirty days.

Junior Physicist Wanted in Bureau of Standards

THE United States Civil Service Commission announces that an open competitive examination will be held throughout the country on June 6. It is to fill vacancies in the Bureau of Standards, Department of Commerce, for duty in Washington, D. C., or elsewhere, at entrance salaries ranging from $1,200 to $1,500 a year, plus the increase of $20 a month granted by Congress.

Applicants must have graduated with a degree from a college or university of recognized standing with the completion of at least 118 semester hours, or be a senior student in such an institution, and furnish proof of actual graduation within three months from the date of the examination. Undergraduate work must have included a course in the optional subject selected. Applicants must choose at least one of the following subjects: Heat, electricity, mechanics, optics, radio, physical metallurgy.

Competitors will be examined in the subjects of general physics, mathematics through calculus, practical questions on each optional subject chosen, and education, training, and experience. Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or the secretary of the board of U. S. civil service examiners at the post office or custom house in any city.

This Combination Completes any RADIO RECEIVING SET

MAGNAVOX

TO own a good receiving set without Magnavox equipment, is like having your house properly *wired* and then using only small, feeble candle-power lamps in the sockets!

Whether placed in the average living room or large dance hall, Magnavox Radio floods the desired area with clear, resonant music or speech—its volume perfectly controlled from the Magnavox Power Amplifier constructed specially for it.

Magnavox R-3 Reproducer and Model C 2 Stage Power Amplifier - $90.00

R-2 Magnavox Reproducer with 18-inch horn: the utmost in ampl fying power, for store demonstration, large audiences, dance halls, etc. **$60.00**

R-3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. **Price, $35**

Model C Magnavox Power Amplifier insures getting the largest possible power imput for your Magnavox Reproducer. 2 stage **$55**
3 stage **$75**

Magnavox Products can be had of good dealers everywhere.

Traded His Bed for a Morris Chair—Whoopee!

From J. E. Bradley, Box C, Justin, Texas

Have finally traded my Bed for a Morris chair, and can stay with 'em until day lite. Below is my log for my work on Monday night, 3-19-23. Left out several stations under 300 miles distance.

Call, Time, Program, Town, Miles

KSD—8:45—Announced, Market Conditions. St. Louis, Mo., 575.
WDAP—8:46—Trombone Solo, Chicago, Ill., 825.
WOS—8:47—Stephens College Glee Club, Jefferson City, Mo., 500.
WOAN—8:52—Singing. Lawrenceburg, Tenn., 600.
KLZ—8:54—Announcement, Denver, Colo., 625.
WCAY—8:58—Vocal Solo, Lady Playing own accompaniment, Milwaukee, Wis., 880.
KDKA—8:59—Band Stars & Stripes Forever. March, Time Signals, E. Pittsburgh, Pa., 1100.
WJZ—9:00—"Army Nite" Band. Medley old time tunes, Newark, N. J., 1425.
KFAF—9:10—Orchestra, Denver, Colo., 625.
WBL—9:12—Announcement, Anthony Kansas, 300.
KDYS—9:20—Vocal Solo "Man," announce Health Talk "Week," Great Falls, Mont., 1250.
WGM—9:30—Announce—Atlanta, Ga., 750.
Frank H. Jones—9:40—Orchestra "You Gave Me Your Heart" and Duet Hawaiian Guitar. Solo Hawaiian Guitar; line off 10:30 Cuban Time; Culiozna, Cuba, 1275.
KFDL—10:10—Vocal Solol, woman; Bert Wells at piano, Denver, Colo., 625.
KGW—10:37—Opera Play "12 Pounds," Portland, Ore., 1575.
WLAG—10:44—The Bachlor 4 Quartette, "Kentucky Babe," Minneapolis, Minn., 825.
WSB—10:45—Rochovels Program, Atlanta, Ga., 750.
WDAJ—10:47—Vocal Solo (Man), College Park, Ga., 750.
KHJ—11:07—Piano Solo, small girl sings and plays piano, Los Angeles, Cal., 1175.
KFDB—11:27—Orchestra "When the Leaves Come Tumbling Down," test program, San Francisco, Cal., 1400.
KFI—11:44—Messenger Boy Playing Harmonica, Los Angeles, Cal., 1175.
WDAF—11:45—Nite Hawks, Kansas City, Mo., 460.

Total number of miles, 19,465.

I keep a log like this every night I listen in.

It will be interesting in the future to look back and see what we listened to in the year 1923, won't it, eh?

I send greetings to all the DX Fellows. *Are there no Lady Dx'ers???*

I am still using my old 2-WD-11 tube set and it is hitting on all 2.

* * *

A One Night's Record

From Osborne Hinckley, 2436 W. 33d Ave., Denver, Colo.

I am sending you my DX record of the stations that I head in one night. I use a very simple hook-up, having only a tapped coil and a variable condenser besides the usual socket tube rheostat and grid leak. The first night I had this set I tuned in the following stations: KFEP, Denver; KDZQ, Denver; KLZ, Denver; KFAF, Denver; DD-5, Denver; WFAA, Dallas; WMZ, Memphis; WDAF, Kansas City; KSD, St. Louis; WLK, Indianapolis; WLAG, Minneapolis; WAAP, Witchita; WOC, Davenport; WDAP, Chicago; KMY Oakland; KDYL, Salt Lake City; KPO, San Francisco; KFI, Los Angeles; KHJ, Los Angeles; KGW, Portland, Ore.; KFZ, Spokane, Wash.

With this set I cannot tune the Denver stations out entirely when some other station is real close. But the interference is so weak that it does not bother long distance much. The stations mentioned above were heard in one night.

* * *

THE editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

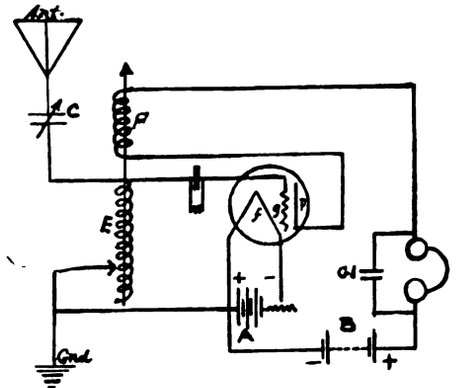
Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

He Touched the Right Spot and —Comes Back with More

From Frank P. McCullen, 210 West State St., Trenton, N. J.

MY hook-up, you published in the RADIO WORLD of the 24th, and my word to the effect that I would answer questions on hook-ups and how to overcome AC hum by using lights and a condenser in series on the 110 volt A.C. house circuit. Replacing the "B" Battery.



Mr. F. P. McCullen's single circuit receiver, which while conventional, gives good service.

Well! I have received 54 letters and numerous cards, requesting information, but I am game to the core. I am sticking it out answering and each day brings in more. I'll have to hire a stenographer if letters keep on coming in at the rate they are.

Have tried out another single circuit regenerative hook-up with W-D 11 tube, and in one evening picked up the following stations: WKY, WBAP, WDAF, WWAJ, CFCA, KSD, WJZ, KDKA, WGY, WFAA, WMAG, WLAG, KGW and the Atlanta Journal and Atlanta Constitution. This is not exceptional with good radio parts and above all, careful making—so many amateurs put too much speed in the making of a machine. I am sure anyone will heartily agree with me in this and also advise less speed—a few days longer makes a better job and you will never regret it.

Enclosed find hook-up that this record was made with and if there are any comments why fire away. I am ready. Yours for bigger and better radio.

With the Only Set in Town

From M. R. Smith, Gimli, Manitoba

HAVING read the records of the DX boys, I thought I'd send in mine. Mine is the only set in town. I have a single circuit, regenerative using no amplification. The following are some of the stations heard since January 30th: KWH, Los Angeles; WFAA, Dallas; WBAP, Forth Worth; KDKA, Pittsburgh; WHAZ, Troy; WHAS, Louisville; WWJ, Detroit; WLW, Cincinnati; also, WOC, WOI, WHB, KLZ, WFAF, WDAF, WCX, KDYS, KSD, WMC, WHA, CFAC, CKCK, CJCG, KYW, CKY, CJNC, WLAD, WLAG, WDAP, WAAP, WOS, WCAS.

* * *

Could Be Better, Could Be Worse, So 's 'Nuff

From A. K. Siler, Jr., 308 S. Narbeth Ave., Narberth, Pa.

I WISH to submit to the DX Nite Owls the following list of stations which I received since March 17. I listened only an hour each night and got all the close-by stations, using only one bulb (UV200), although I have a three-bulb set: KFDB, KDKA, WBZ, WOC, WMAQ, WLAG, WDAP, WLAK, WOAX, WHAZ, WHAM, WJAS, WJAX, WGR, WGI, WDAF, WHK, WHAS, WAAM, WNAC, WOAT, WEAS, KOP, WFAQ, WMAK, WOAW, WGM, KSD.

* * *

"Sparks" Comes in on DX

From C. Previti, Operator, S. S. Ponce

WISH to submit some DX work done on a neat home-made set costing $35, using an exceptionally sensitive circuit.

Have heard following: KHJ, WOC, WDAP, KYW, WHB, WWJ, KSD, WHAS, KDKA, WMAE, WGY, WHAZ, PWX, WSB, WJZ, WEAF, WOR, WPI, WFI, WKAQ, WOO.

These are only a few of the long distance, as other stations such as Denver, Cincinnati, Cleveland, Springfield, Mass., have been heard but am not sure of call letters.

All above stations have been heard plainly and practically every night on detector only, trip after trip during my week's stay in Porto Rico. The work which I can do on detector only using present set and circuit were never done by my former regenerative set and two steps. All stations were heard both during last summer and this winter, but as you know that during summer time atmospherics are fierce in the tropics.

* * *

67 On a WD-11

From Frank Baker, 420 South 5th St., Petersburg, Ind.

I HAVE read many DX records in your magazine, and am sending mine.

My set is a single-circuit regenerative, using one WD-11 tube, one variocoupler, 43-plate V. condenser, 3,000-ohm. phones, leak, etc.

The stations are as follows:

WJZ, WHA, KFAF, WCK, WOS, WOI, WDAJ, WAAF, WEAP, WEAF, WWJ, PWX, WCAD, WFAA, WLAG, WMAQ, WGF, WGM, KSD, WWJ, WMC, WSY, WSB, WBAP, WIAO, WCX, KDKA, WGY, WDAP, WHB, KYW, WOC, WOR, WHAS, WDAF, WIP, WTAS, WLW, WAAP, WBAV, WPA, WJAX, WLK, WOAI, WAAJ, WRAY, WGI, WKY, WGL, WDAE, WSAJ, WHAZ, 9DMB, WMAV, WMAT, WHK, 8YO, WIAR, WBZ, KFI, WCAE, KHJ, WBL, WMAK, WHAH.

The set was constructed at home.

Protection of Vacuum Tube Filaments

THE radio fan is apt to experience disappointment when he finds that the high voltage leads from the "B" battery have been accidentally connected across the filament posts of his receiver and one or more tubes are burned out. Although the normal life of the average radiotron filament is considerably more than one thousand hours, it requires but an instant to destroy this delicate filament when excessive voltages are applied to its terminals.

When filaments are shorted across a 20, 40 or 60 volt battery in new condition the burn-out requires but a fraction of a second, and unless the user happens to be inspecting the tube at the instant of the flash the damage would not be discovered until the set was used again. It is a very easy matter to protect tube filaments by either of the following means:

(a) Insert a 100-ohm (non-inductive) resistance *for each 22-volt block of "B" battery* in the circuit next to the positive terminal of the "B" battery. This resistance may be left permanently in the circuit without any effect whatsoever on the normal life of the receiving set.

(b) Probably the most convenient form of resistance is a 25-watt, 110-volt tungsten lamp, which will provide sufficient protection for plate voltages up to and including 100 volts. This resistance automatically increases with the current so as to act, in effect, as a protective ballast lamp.

Radio Increases Church Attendance

THAT the broadcasting of religious services has increased church attendance, that radio has been a real help to the work of the church and has brought satisfaction and comfort to hundreds and thousands of people, is the opinion of the ministers of Schenectady, N. Y., who have been cooperating with M. P. Rice, director of broadcasting of the General Electric Company, in the transmission of church services.

From the inauguration of the radio church service by WGY, October 1, 1922, the studio management has cooperated very closely with the Ministerial Association of Schenectady, N. Y. The Ministerial Association, which is made up of the pastors of all the evangelical churches, named a committee of which the Rev. Robert W. Anthony, pastor of the First Presbyterian Church, is the head, to assist the studio manager in the assignment of clergymen for the vesper services and in planning the order in which the services of different denominations should be broadcast.

In nearly every case the morning and evening services of a church are broadcast. The church is connected to the transmitting equipment of the broadcasting station by means of land wires. Two microphones are placed in the church, one for the preacher and another for choir and organ. But for the presence of the microphones the church congregation would not be aware that the service, ordinarily limited to the four walls of the church, was going out into thousands of homes over a great territory.

No More Loose Phone Connections

Manufactured by the Saturn Mfg. & Sales Co., Inc., 48 Beekman Street, New York City.

A PLUG recently put on the market by this firm incorporates a novel and useful feature. By the use of this plug all screws and slip connections are entirely eliminated, it only being necessary to slip the phone tips into the proper holes in the back. A tooth-slip of hardened copper takes hold of each tip, and the harder you pull on the cord the more solid the grip exerted on the tip itself. When it is desired to change the phone tips, or remove the phones from the plug, all that is required is to press a small projection on the back of the plug and the tips are released. Besides this novel idea it is also made up of the best materials, and the brass nipple and sleeve of the plug itself is machined and polished to a fine degree. It is a very well manufactured piece of apparatus of its type.

Radar Adjustable Leak

THE Radar Instrument Company, 224 Market Street, Newark, N. J., is manufacturing an adjustable leak which is unique in design and has some interesting features. The Radar is entirely enclosed, so that its parts are protected from dust and dampness. It can be mounted inside of the panel with its control knob on the outside of the panel, and it can be fastened on the base without requiring a standard mount. These features and the fact that the Radar fits any standard grid leak mount should make it a very popular article.

New Distributors of Radio Supplies

ONE of the largest automobile supply distributors in the country—the Times Square Auto Supply Company, New York City—has added a radio supply department to its business.

Amsco Products, Inc., is a New Combination

ON May 1, 1923, the Mortimer Radio Corporation, manufacturers of the "Melco Supreme" radio-frequency receiving set, and the Advance Metal Stamping Company, manufacturers of high-grade parts, both of New York City, will consolidate and be known in the future as Amsco Products, Inc.

The "Melco Supreme" radio-frequency receiver will continue to be marketed under its own name, while a complete line of parts will be available at all good dealers under the "Amsco" brand. The new home of Amsco Products, Inc., will be in the Fairbanks Building, Broome and Lafayette Streets, New York City. Ideal manufacturing facilities will enable this concern to give even better service than was possible before the consolidation.

Short Cut Antenna an Ingenious Device

THE Short Cut Radio Corporation, 243 West 54th Street, New York City, have just brought out a new product, "Short Cut Antenna," which they claim eliminates the aerial as well as loops, electric light plugs, etc. The nature of the "Short Cut" is that of a super-condenser though its peculiar and valuable properties are due to certain patented features. The fact that the product makes a set portable in addition to clarifying signals, eliminating code and reducing interference troubles generally to a minimum, should make it of especial interest to dealers, now that the summer season is coming on.

"The A, B, C of Radio"

RADIO enthusiasts will be interested in "The A B C of Radio," which Modells advertise for distribution to RADIO WORLD readers. This is a 62-page book, replete with diagrams and drawings, and was written by the former editor of a popular scientific magazine. It is claimed that 200,000 copies of "The A B C of Radio" have been sold at the retail price of 25 cents. Modells have purchased a quantity for distribution to RADIO WORLD readers, who will be placed upon the mailing list which this concern keeps on file. There is a charge of 10 cents to cover cost of forwarding. An announcement regarding this is made by Modells in this issue of RADIO WORLD.

Neon Lightning Arrester

THE Neon lightning arrester, manufactured by the Neon Lamp Works, 62 West 114th Street, New York City, makes use of neon gas, which is absorbed from the air by a very complicated chemical process. Neon gas is an excellent electrical conductor, and its resistance, compared with that of air, is 1:165. This means that the discharging efficiency of a lightning arrester with neon gas is excellent, and it is guaranteed to discharge over 220 volts. The Neon lightning arrester can be also used as a rectifier for small currents.

Blueprints of Sets and Circuits

IN reply to hundreds of inquiries, RADIO WORLD desires to state that it does not supply blueprints of sets and circuits published in its columns unless the articles in question so state specifically. This announcement is made to save time and avoid disappointment to readers.

Private Radio Broadcasting Starts in Japan

SEVERAL private Japanese concerns are now permitted to broadcast government reports, speeches and music by radio, the government having relaxed its rigid policy, advices from Japan to the Department of Commerce state. Only a few financially sound companies in Tokyo and Osaka, and perhaps one or two other large cities, will be licensed. A broadcasting tax is required by the government after April 1. The companies will charge subscribers a fee for the service rendered, which the government will collect, returning a percentage to the broadcasters. Individual users of broadcasting and receiving sets will not be permitted to communicate with each other, it is stated. Complete receiving sets will cost between 20 and 30 yen, or between $10 and $15, it is anticipated by Japanese experts.

Milwaukee Radio Amateurs' Club Active

THE Milwaukee Amateurs' Radio Club has been incorporated under the laws of the State of Wisconsin as a non-stock body, and its name changed to The Milwaukee Radio Amateurs' Club, Inc. The incorporators were L. S. Baird, C. N. Crapo, and Attorney L. J. Topolinski, the society's general counsel, through whose efforts state incorporation was brought about. In addition to including the past purposes of the club and those of the American Radio Relay League, Inc., the articles of organization provide that the society may own and operate an amateur radio station and may associate itself with the A. R. R. L. as a Milwaukee section or local chapter.

Meetings continue to be held weekly at 7.45 P. M., Thursdays, in the Trustees' Room of the Milwaukee Public Museum. Business Manager L. S. Baird recently received the appointment as A. R. R. L. Central Division Publicity Manager, and in order to devote proper attention to his new duties his chairmanship of the Meetings and Papers Committee has been transferred to H. F. Wareing, president of the society. This committee is now arranging for a series of lectures on timely radio topics. R. E. Lathrop, 9ATX, of the club's technical committee, represented Wisconsin at the Michigan State A. R. R. L. convention held at Flint, Mich., and upon his return gave the Milwaukee club members a lengthly report.

Radio frequency amplification has been the subject of several general discussions at meetings, and a paper entitled "Intervalve Radio Frequency Transformers" was presented by I. H. Strassman, 9AHO. Mr. Strassman, who is A. R. R. L. City Manager, has also reported from time to time the progress being made in ridding the air of unlicensed stations. These offenders have operated much to the discomfort of both the radiophone listeners and the amateurs.

Partial Program from WGI (360 Meters)

STATION WGI, operated by the American Radio & Research Corporation, Medford Hillside, Mass., announces the following program for the dates named:

Saturday, April 21, 1923

6:00 P. M.—New England Weather Forecast, furnished by the U. S. Weather Bureau. Late News Flashes, Early Sports — Boston American.

6:15 P. M.—Condition of the Massachusetts Highways, furnished by the Automobile Legal Association.

6:30 P. M.—Boston Police Reports—Boston Police Headquarters. Amrad Bulletin Board.

6:45 P. M.—Code Practice, Lesson Number Thirty-eight.

8:00 P. M.—Evening Program.

1. Third of a series of talks on New England Problems, under direction of the New England Business League.
2. Concert by Coyne's Orchestra of Lawrence; Mr. Matthew T. Coyne, Director.

Sunday, April 22, 1923.

4:00 P. M.—Twilight Concert.

8:30 P. M.—Federation Church Service, conducted by Rev. Fred Alban Weil, Pastor of the First Parish Church of Quincy; assisted in the music by the Quartette of the Church.

9:00 P. M.—Musicale by the Quartette of the First Parish Church of Quincy. Mrs. James H. Slade, Soprano; Miss Angela C. McCarthy, Contralto; Winthrop D. Webb, Tenor; John E. Greene, Bass; John D. Buckingham, A.G.O., Director and Organist.

Broadcasting Schedule of the Detroit News

The present broadcasting schedule of the Detroit News, Detroit, Mich., station WWJ, is as follows, the regular evening program beginning at 7 o'clock one week and at 8.30 the next week, alternately:

Week days, every day in the year, except as otherwise noted:

9.30 to 9.45 a. m.—Hints to housewives.

9.45 to 10.25 a. m.—Health or economic talks (Uncle Sam).

10.25 to 10.30 a. m.—Weather report.

11.55 to 12.00 noon—U. S. Naval observatory time signals.

12.05 to 12.45 p. m.—Impromptu musical selections (usually).

3.00 to 3.30 p. m.—Detroit News Orchestra (usually).

3.30 to 3.35 p. m.—Weather report.

3.35 to 4.15 p. m.—Market quotations.

5.00 to 6.00 p. m.—Miscellaneous, markets and Government messages.

Week nights except Saturday: For weeks of April 1, April 15, April 29, etc., 7.00 to 8.30 p. m.—Concert. For weeks of April 8, April 22, etc., 8.30 to 10.00 p. m.—Concert.

Thursday special—On alternate Thursday nights this station is now giving a program between 11 and 12 p. m. for the special benefit of listeners at distant points. This "midnight special" falls on those weeks which have regular programs from 8.30 to 10.00, as scheduled above.

The Detroit News does not broadcast on Saturday nights, this omission being a courtesy to Detroit people who wish to tune in distant stations.

Sundays—Sundays of April 15, April 29, etc., 11.00 a. m.—Church services at St. Paul's Episcopal Cathedral. The Very Rev. Warren L. Rogers, dean, is usually the preacher. 5.30 p. m.—The Detroit News Orchestra. Sundays of April 8, April 22, etc., 2.00 p. m.—Detroit News Orchestra. 7.30 p. m.—Church services at St. Paul's.

Western Union Feels Radio Competition

ALTHOUGH the business of the Western Union Telegraph Company was larger and more profitable in 1922 than in 1921, President Newcomb Carlton devotes a considerable portion of his annual statement to stockholders to a résumé of the competition with its cable business caused by the rapid development of radio communication. President Carlton says in part:

"Radio has made substantial progress during the year, not only in improved service, but in capturing additional business with low rates from the cable companies. The advantages still lie with the cables, but they need waking up. The cable art has not advanced as it might have advanced, and as it must advance, under the stimulus of a cheaper means of communication. Whether the radio is in fact cheaper than the cables cannot be answered now, but this much can be said: 'That the present radio rates were not based on the cost of operation. These rates were arbitrarily fixed to attract business.'

"Now that business has been attracted, and the investment necessary to transmit business between the United States, Great Britain and Europe is mounting to important figures, the investor will no doubt show an increasing interest in the question of the adequacy or inadequacy of radio rates. These rates between the United States and Europe are about 30 per cent. less than the cable rates, and, principally because of their lower charges, the radio has captured 20 per cent. of the United States-European business.

"It has been our view that the resources of radio will be combined with those of the cable in the development of a system of world communication that will place the United States first among all countries for capacity and reasonable rates, provided the government will adopt a progressive and business-like method of dealing with cable companies.

"We are disposed, therefore, to think of the radio in terms of a great medium of transmission, and as a potential ally rather than in terms of a continuing competitor. Whatever way the question may be decided, and regardless of the downward trend of rates, it should be borne in mind by Western Union shareholders that more than 90 per cent. of the income available for dividends in 1922 came from their nation-wide system of land line services, which does approximately 85 per cent. of the land line telegraph business in the United States. In fine, if there had been no net income from the cables in 1922 the company's net income would not have been materially reduced."

The operating revenues of the company for 1922 are reported as $105,447,748, compared with $104,155,113 in the previous year. Net operating revenues totaled $13,796,473, against $10,196,029. After crediting other income, deducting interest charges and appropriating $2,000,000 for the development of ocean cables, there was a balance of $11,158,180 available for the capital stock, equal to $11.17 a share earned on the $99,817,000 stock outstanding. In 1921 the balance was $9,633,808, equal to $9.65 a share on the stock. The general balance sheet on December 31, 1922, showed net current assets of $38,393,265 and net current liabilities of $26,045,369.

DX Radiomania

THE man who used to grunt and groan and stay awake nights said it was insomnia, but now when he gets to the office looking as though he needed sleep he generally blames it on—"Dawgone, he didn't sign off, and then some blame nuisance butted in and I couldn't get his call." It's all one, whether you call it radiomania or insomnia—it keeps you up just the same.

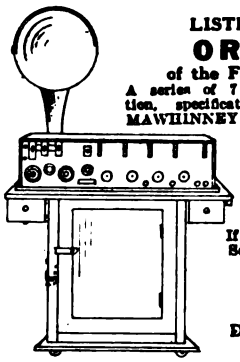
High Speed Communication at Sea

ON the last voyage of the White Star Liner "Majestic" the world's greatest steamship, radio messages were exchanged with shore stations of Radio Corporation of America at speeds of over 80 words per minute when the vessel was 1,000 miles at sea. Ordinarily speeds in excess of about 25 words per minute cannot be attained by hand sending and in order to meet the demands of increasing radiogram traffic created by the large passengers liners, machine sending must be used in which case a given message can be sent and received in one-third the time required by manual methods.

The earlier experiments aboard the "Majestic" permitted only one way high speed transmission, namely, from ship to shore, there being no apparatus on board the vessel capable of receiving high speed transmission. In order to effect *two-way* high speed telegraphic service on the vessel during its last voyage to New York, it was equipped by the Marconi Company with a high speed receiver which worked most satisfactorily. High speed signals were also received from Paris at a distance of eight hundred (800) miles at a speed of 80 words per minute. Wireless press was completely and perfectly recorded by the automatic receiver through medium static from the station of RCA at Chatham, Mass. At the same time that this automatic high speed reception was carried out it was possible for the operator on watch to listen in on the ordinary ship's wave length for general "ship to ship" wireless.

Not only does the use of automatic high speed receiving and sending apparatus enable operators to handle more traffic in less time and thereby provide freedom of the ether for other vessels to operate their radio sets but in addition secrecy of communication is maintained, owing to the great rapidity with which the dots and dashes are transmitted. It is difficult for the average operator to copy over 30 words per minute for any length of time, consequently when working at double speed the telegraphic symbols follow in such rapid succession that they cannot be deciphered.

LISTEN IN ON—Stockton, Cal., or Seattle, Wash.
ORIGINAL BLUE PRINTS
of the Famous MAWHINNEY RECEIVING APPARATUS



A series of 7 blue prints giving in full detail all the necessary information, specifications, and method of construction, and assembling of the MAWHINNEY RECEIVING Apparatus. This is the 5-tube receiving set that picked 5 stations in California, recently written about in Literary Digest and Radio Globe. The Blue Prints tell you in a very simple and clear manner just how to construct a duplicate of MAWHINNEY'S trans-continental receiving set.

If your dealer cannot supply you—

A Revision of the Gibbons Circuit

In RADIO WORLD for March 31, 1923, was published a diagram of a circuit as used by Mr. Earl E. Gibbons, which contains an error.

The potentiometer should be in shunt of the 6-volt A Battery. This puts the detector rheostat in series with the potentiometer from the negative A Battery, which will make it inoperative.

The first and second step rheostats are in series with the potentiometer from the negative A Battery, with positive returns. Thus, the potentiometer being of high resistance, would make the filament controls useless.

In order to correct the error, the potentiometer should be shunted across the 6-volt battery and the polarity of the battery should be changed.

New Use for the Panama Canal

First Bug—"Say Al, you know I picked up Seattle, Washington, last night? Came through great. Three thousand miles. Some stuff for DX, what?"

Second Bug—"Stand by, stand by, brother! You can't tune me to that wave. That's overland, buddy, and the old stuff don't skip over terra firma like she does over the water."

First Bug—"Aw, say! Lay off the QRM! May be my stuff came through the Panama Canal!"

SOMETHING NEW
THE H.K. INDUCTANCE SWITCH

Every one knows the difficulty encountered in drilling holes in a panel for switch points and getting them spaced correctly. The H. K. Multiple Switch does away with this troublesome drilling. Can be mounted on a panel in about the same time it takes to mount a rheostat. Has 15 contact points, each fitted with two nuts for connecting taps from inductance.

Complete, with dial calibrated from 0 to 14.

The new H.K. Inductance switch has many advantages over old style of mounting, namely: This switch has a good bearing, which assures good contact; can be shielded from panel if desired, thereby eliminating capacity effect.

The terminals are placed so wires can be attached with ease. It requires only two holes to mount on panel. Can be used for table or panel mounting. Furnished with Knob and Pointer or Dial. Dial numbered to indicate contact in use.

Price, complete with dial.....$2.00

Special prices to Dealers and Jobbers.

Knoop & Pence Co., Peotone, Ill.

CORRESPONDENTS WANTED BY RADIO WORLD ALL OVER THE UNITED STATES AND CANADA

Send us your name and address and say that you want to become our correspondent. We will show you how you can represent RADIO WORLD in your locality and at the same time make money for yourself. We would particularly like to hear from those who are handling the "Saturday Evening Post."

General Broadcasting Schedule of Station WDAP

THE general broadcasting schedule of Station WDAP, Drake Hotel, Chicago, which is also the official station of the Chicago Board of Trade, is given below. The market reports are sent on 485 meters and the concerts on 360 meters. Following is the schedule for all busiess days:

9:30 A. M.—Receipts and shipments; estimated carlots; local weather report; opening future markets: wheat, corn, oats, rye, barley, pork, lard and ribs.
10:00 A. M.—Future quotations; live-stock receipts and prices.
10:30 A. M.—Future quotations.
11:00 A. M.—Future quotations.
11:30 A. M.—Future quotations.
12:00 Noon—Future quotations and cash grain prices.
12:30 P. M.—Future quotations.
1:00 P. M.—Future quotations.
1:15 P. M.—Musical program by Henry Selinger and the Drake Concert Ensemble.
1:25 P. M.—Closing future quotations and high and low for day; cash grain prices; gross bids for cash grain to arrive.
3:15 P. M.—Closing quotations, Chicago Stock Exchange, by Paul H. Davis & Co.
6:00 P. M.—Closing quotations; news items.

(On Saturdays the closing prices are sent at 12:05 P. M. instead of 1:20 P. M. The Visible Supply changes are sent when posted.)

Regular Concert-Sending Schedule. 10:00 P. M., Tuesday, Thursday and Saturday evenings; 9:15 P. M., Sunday evenings.

Announcement of Special Programs or Features will be made from the Station.

On Tuesday, Thursday and Saturday nights the program is divided between artists in the studio and Jack Chapman's Orchestra, playing dance music in the main dining room of the Drake Hotel.

On Sunday nights the program is divided between exceptional artists in the studio and Henry Selinger and the Drake Concert Ensemble, playing in the main dining room.

Partial Program of WGY for Week of April 22

WGY, General Electric Company, Schenectady, N. Y., will broadcast the music and speeches of the annual dinner of St. George's Society of Albany, N. Y., Monday evening, April 23. The principal speaker will be Captain Kilroy Harris, D.S.O. Captain Harris was king's messenger, and, following injuries received during the war, he was appointed official war lecturer for the British and United States governments.

Sunday, April 22, WGY will broadcast the morning and evening services of the Second Presbyterian Church of Amsterdam, N. Y. In the afternoon, at 4 o'clock, the WGY Symphony Orchestra will give a program, assisted by William Demorest, boy soprano.

William DeMille's play, "Strongheart," will be produced Tuesday evening, April 24, by the WGY Players, headed by Edward H. Smith.

Wednesday evening is "Silent Night" at WGY, and the following night the American Locomotive Company Band will give a concert.

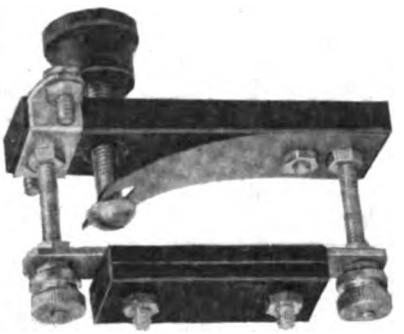
The Commercial Bank Club of Albany will entertain from the General Electric station Friday night, April 27. The program will consist of orchestral numbers, quartet and solo selections. Saturday night, from 9 to 11 o'clock, Cain's Castle Orchestra will play.

New Radio Firms

Barclay Electric Co., New York City, $20,000; Stelz, D. Grossman, J. McCoy; attorneys, Reit & Kaminsky, 305 Broadway.

Imperial Radio Corp., Jersey City, N. J., radio, $500,000. E. Russell Carlisle, R. E. Albin, New York; C. E. Grant, Canada.

Another Horton Triumph



Horton Variable Grid Leak

Unbroken Range 0-9 Megohms

1000 Variations by fine Vernier adjustment. No pencil lines or leaky, smeary graphite to harden with age. Once set it stays set until readjusted. Nothing shows outside panel but small Bakelite adjustment knob, thereby completely eliminating body capacity and howl.

May be used with any type Fixed Condenser.
Guaranteed for 3 Years.
Makes Radio Reception a Pleasure.
For Sale by all leading dealers.
Price $1.00—With Condenser add 25c.

A Plan for Selling Radio Sets to American Legion Posts

RADIO dealers and retailers should be interested in the plan described below by which the J. Burt Pratt Post, of the American Legion, at Virginia, Minnesota, financed the purchase of a radio set. A similar plan might be proposed by dealers to American Legion posts in their local territory. A. R. Hulbut, publicity officer of the post named above, sends to the American Legion Weekly the details of the plan as follows:

"Three hundred shares of stock were issued to sell at one dollar a share. Any member could buy up to five shares. After enough shares were sold we bought an outfit and a radio club was formed. The post then agreed to take up the shares at their face value, merely transferring them into dues accounts. This was not done all at once; in fact, it is being done only as the post gets money enough in its treasury so it can spare the dues, but the members of the radio club know that eventually the post will repay them for their stock. Although we have no radio in the club at present, we are not worrying, because we only got rid of the old one to buy a better one.

"I would recommend the above procedure to any post, and have no hesitancy in stating that radio will make the post clubrooms a greater gathering place than ever. We in Virginia had the opportunity to hear a snappy talk by Department Adjutant Stafford King by radio just a few days ago, the significance of this being that eventually every Legion post will have a set and we will find it possible to have a Legion radio night throughout the country, and can open our meetings with talks from national as well as department officers while we are sitting right in our own clubrooms.

"I have often thought of a National Headquarters broadcasting station at Indianapolis, which I believe would do more to advertise the Legion than any other medium. Such a station would now reach over a million people and would eventually mean a radio in every Legion post. Imagine a night, known as 'Legion Meeting Night' throughout the United States, when every post would meet and could hear a message from the National Commander."

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

"Twice as Near Is Half as Far"

WORDS spoken in a public hall in Schenectady, N. Y., reached a radio listener in San Francisco, Cal.—2,550 miles away—before they were heard by a listener 150 feet from the speaker.

That statement looks a bit fantastic, but it is mathematically true. The apparent absurdity becomes reasonable when it is realized that the speed of sound is 1,126 feet per second at a temperature of 69 degrees Fahrenheit, and the speed of electrical vibrations, or radio waves, is 186,000 miles per second.

The listener in the back of the hall in Schenectady—150 feet from the speaker—heard the words in 0.1332 seconds.

A microphone connected to the radio transmitting equipment of WGY, the General Electric Company station, was two feet in front of the speaker, and picked up the words in 0.002 seconds.

Time required to transform sound waves into electrical energy, 0.002 seconds.

Time required for electrical vibrations or waves to pass from Schenectady to San Francisco, 0.0137 seconds.

Time required at receiving end to convert electrical vibrations into sound vibrations, 0.001 seconds.

Total elapsed time from the speaker in Schenectady to the radio listener in San Francisco, 0.0187 seconds.

Listener in hall heard words in 0.1332 seconds.

The period of time elapsing between the spoken word and its reception via radio, 2,550 miles away, can be illustrated as follows: 0.0187 seconds is time required for a spectator at a baseball game to hear the impact of bat against ball when he is standing twenty-one feet from the batter.

BUILDERS AND EXPERIMENTERS. Do you know that the Reflex circuit is one of the most interesting circuits to construct? You can not guess how much fun you are missing if you fail to try out at least one of these circuits. See RADIO WORLD issues of Feb. 24 and March 3. They contain two fine articles by W. S. Thompson, with plenty of new Reflex circuits to experiment with. Don't miss these! 15c. a copy. RADIO WORLD, 1493 Broadway, New York City.

TWENTIETH CENTURY BOOK OF RECIPES, FORMULAS AND PROCESSES—Edited by Gardner D. Hiscox. This book of 800 pages is the most complete book of recipes ever published, giving thousands of recipes for the manufacture of valuable articles for every-day use. Hints, helps, practical ideas and secret processes are revealed within its pages. It covers every branch of the useful arts and tells thousands of ways of making money and is just the book everyone should have at his command. The pages are filled with matters of intense interest and immeasurable practical value to the photographer, the perfumer, the painter, the manufacturer of glues, pastes, cements and mucilages, the physician, the druggist, the electrician, the dentist, the engineer, the foundryman, the machinist, the potter, the tanner, the confectioner, the chiropodist, the manufacturer of chemic novelties and toilet preparations, the dyer, the electroplater, the enameler, the engraver, the glass worker, the gold-beater, the watchmaker, the jeweler, the ink manufacturer, the optician, the farmer, the dairyman, the paper maker, the metal worker, the soap maker and the technologist in general. A book to which you may turn with confidence that you will find what you are looking for. A mine of information up-to-date in every respect. Contains an immense number of formulas that everyone ought to have that are not found in any other work. New edition. 807 octavo pages. Cloth binding Price, $4.00. The Columbia Print, 1493 Broadway, New York City.

EXCHANGE LETTERS with friends everywhere. Pleasant pastime. Information for stamp. Smith, Box 3125, M. Portland, Ore.

FOR SALE—Reinartz set in cabinet, $15. M. Stumpfel, Lake Mahopac, N. Y.

FOR SALE—Two-step amplifier in cabinet, $20.00. DeForest Audio Transformer, $4.50. Raymond Schlegal, 1118 N. Negley Ave., Pittsburgh, Pa.

IMPROVED MADE TOYS WANTED—MANUFACTURERS on large scale. Also houseworkers to manufacture metal toys and novelties. Thousands needed of Whistling Birds, Wild Animals, Crowing Roosters, Automobiles, Baseball Players, Statue of Liberty, Indians, Toy Soldiers, Cowboys, Bathing Girls, Souvenirs, and others. Wonderful opportunity. We guarantee Casting Forms furnished to manufacturers with complete outfit from $3.50 up. No tools or experience necessary. Thousands paid for finished goods. Spot cash. Contract orders given out. THE IMPROVED METAL CASTING CO., 342 East 145th St., New York.

CASH FOR OLD GOLD, Platinum, Silver, Diamonds, Liberty Bonds, War, Thrift, Unused Postage Stamps, False Teeth, Magneto Points, Jobs, Any Valuables. Mail in today. Cash sent, return mail. Goods returned in ten days if you're not satisfied. OHIO SMELTING CO., 337 Hippodrome Bldg., Cleveland, Ohio.

THE ANNIVERSARY NUMBER of Radio World was increased in size and an exceptional issue. A few copies left at 15c. each, or you may start your subscription with that number. Radio World, 1493 Broadway, New York.

SWISS VOLTMETER 3-0-3. Stained wood case, brass hinges, catches and spring terminals on Ebonite panel, carrying strap, three gravity cells; weight eight pounds, 11x8½x5½x4½ inches. Best cash offer or consider exchange. Fred P. Honnan, Halifax, Canada.

BEAUTIFUL WHITE TEETH—YOU can have beautiful white teeth without toothbrush, pastes or powders. No matter how badly discolored your teeth are, this harmless secret will make them white. Economical, sanitary. Price, 25c. AMERICAN SALES CO., Box 1278, San Francisco, Calif.

RADIO FREQUENCY AMPLIFICATION. Get the best results with radiophone reception. Long distance reception, purity and volume of tone reproduction, static reduction and selectivity. We have working plans, blue prints, with exact specifications of parts to assemble to construct a three tube set. Gives marvelous results. Save worry and experimentation in building one of these sets. Any amateur can build. Guaranteed results. Sent for $1.00, postpaid. Research Laboratories, Carthage, Mo.

RAND-McNALLY RADIO MAP OF UNITED STATES—Is 28 x 30 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover. Price, 35c. The Columbia Print, 1493 Broadway, New York City.

Manufacturers' Representation Wanted

EDITOR, RADIO WORLD: The writer, with others, is forming a company to distribute radio apparatus and supplies in northeast Ohio and northwest Pennsylvania.

Can you place me in touch with manufacturers who would desire exclusive representation in the territory mentioned? Have manufacturers quote jobbers' prices, and give complete information necessary in first communication.

Yours very truly,

Capsules Used to Protect Crystals in Shipment

A NOVEL idea has been put into effect by the Specialty Service Company, 552 Pacific Street, Brooklyn, N. Y., in the protection of their DX radio crystals during transit to purchasers. The crystal and a circuit diagram showing how to use the crystal set in connection with a supplementary tube are packed in a transparent capsule. This affords ample protection for the crystal and makes a package attractive in appearance. It is encouraging to find manu-

NATIONAL AIRPHONE IMPROVED "GOLD-GRAIN" DETECTOR

Highly Recommended For

CRYSTAL and REFLEX SETS

This detector is the greatest crystal detector in existence. It reproduces voice and music in natural color of tone, clear and loud, without distortion. You will be surprised at the wonderful results and satisfaction it gives. Takes the worry away—no more tinkering with catwhiskers.

Write for Diagram of Circuit on Reflex Construction.

YOU ARE PROTECTED BY THIS GUARANTEE

Should any National Airphone or "Gold-Grain" Detector not be in first-class condition when purchased, and within 10 days you return it to us unopened, or in unbroken condition, we will repair it or send you a new one free of charge.

HIGHEST TESTIMONIALS

From the Public, and awarded Certificate of Merit by the Laboratories of RADIO NEWS, THE EVENING MAIL and N. Y. TRIBUNE.

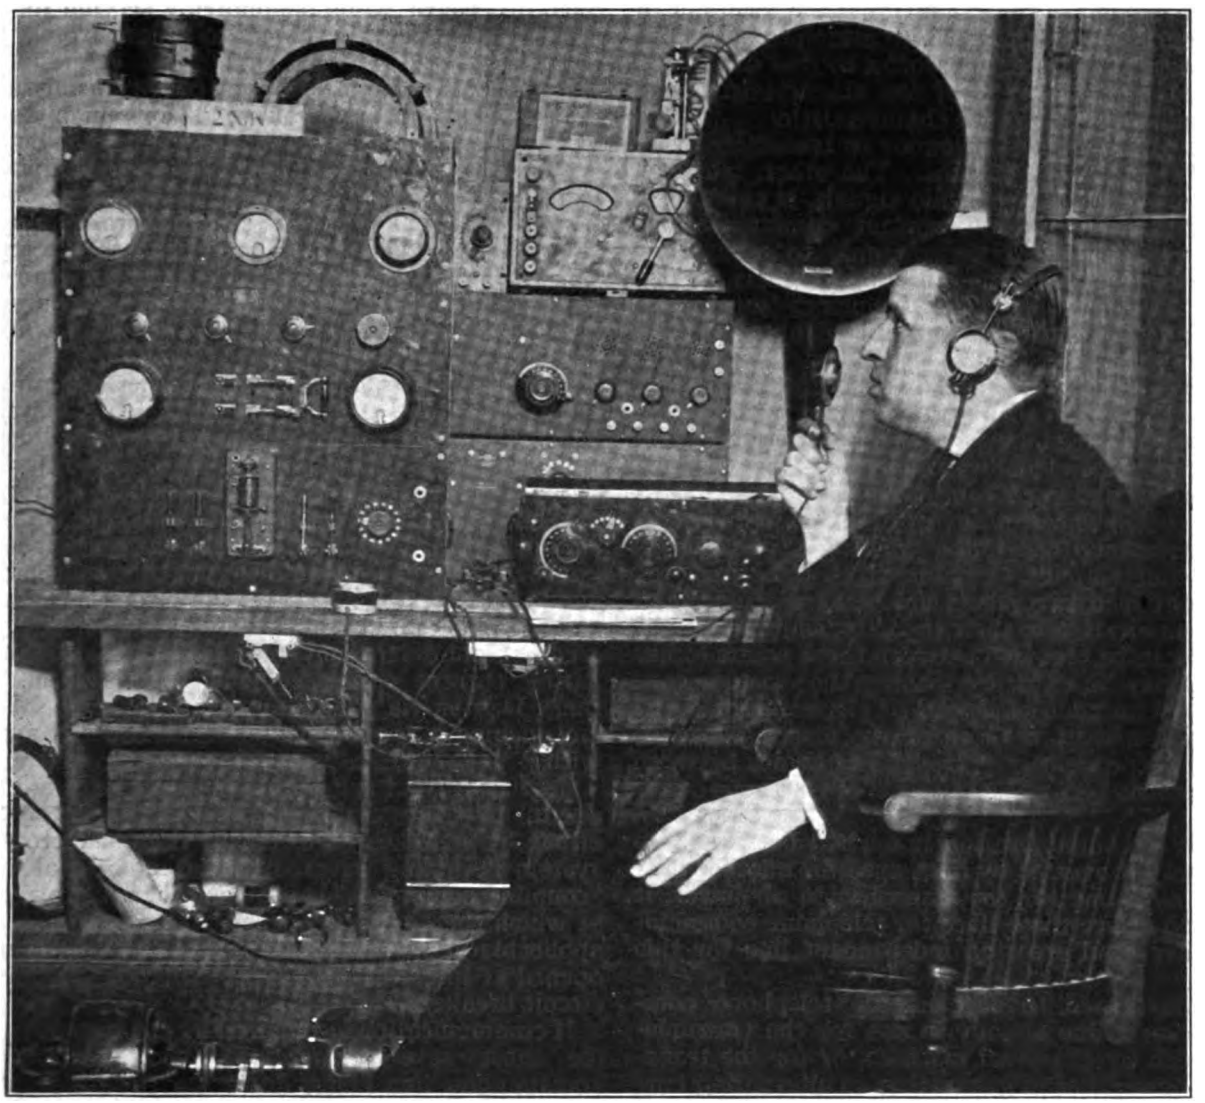
A Notable Member of Radio's Higher Circles

By William Silver



(C. Photonews, N. Y.)

Transmitting and receiving equipment of L. M. Cockaday, one of the prominent amateurs of the United States. Mr. Cockaday, who is operating his radiophone set, has just perfected a new four circuit receiver shown below his right hand.

ONE of the best known amateur radio stations in the United States is 2XK, operated by Lawrence M. Cockaday, and located at 1522 Jessup Avenue, New York City. It is a station that has done remarkable work in both telegraphy and telephony and has established several records in both for the other amateurs to shoot at.

The illustration shows the receiving and transmitting equipment of 2XK as well as its owner. The transmitter, situated on the left hand side of the table, is rated at 200 watts maximum, uses six tubes, (four 50-watt tubes and two five-watt), and can be used for either telephony or CW. Power for the plates is furnished by the motor-generator shown on the floor.

Mr. Cockaday has just perfected a four circuit tuner, shown directly to the right of the transmitter at the front of the table. With this receiver he has picked up stations all over the United States, Canada, Cuba, and Porto Rico. The circuit is at present a secret, because of certain technical parts that have to be brought to a higher standard of perfection before the receiver is really complete.

The regular receiving equipment is shown directly back of the new receiver.

Features of Carrier Current Telephony

By B. R. Cummings

Radio Engineer, General Electric Company

IT is a matter of common knowledge that a single electrical conductor can be made to be a part of two or more electrical circuits and function in each circuit simultaneously. It is possible, for example, for a single conductor to carry both alternating and direct current, or two or more alternating currents of different frequency characteristics, simultaneously.

These currents do not exist independently in the conductor, however, and at any instant the current flowing is the sum of all component currents.

While the current in the conductor is the resultant of individual currents, it is possible to attach to such conductors suitable groups of apparatus, so that one group will respond to the current of one characteristic, and the other to that of the other characteristic.

This fact is somewhat analogous to transmission by radio at different wave lengths. The ether, which is the medium which conveys radio signals, is carrying a very great number of independent communications simultaneously, although we are able to adjust our radio receivers so that we can select signals at one frequency, and, with sufficient frequency separation, hear nothing that is being transmitted at other frequencies.

So that, while signals carried by wire are transmitted by conduction rather than by radiation, a conductor may be made the medium whereby a great number of signals having individual characteristics are carried simultaneously, and each can be received by appartus which is adjusted to select any of the incoming signals.

This phenomenon has found growing application in communication systems. For example, if a group of wire lines between two points are being used for telephone communication to their capacity, additional communication can be provided between these points either by erecting new lines, or by making the existing conductors carry an additional load of characteristics differing sufficiently from those of the existing load to permit its independent reception. The choice between the two methods becomes a question of economic selection.

Similarly, if communication is desired between two points already converted by lines used for another purpose, such as a line for the transmission of power, it is possible to utilize these lines for telephone communication, rather than erect an independent line for this purpose.

The method used to superimpose telephone communication on a line already in use for the transmission of speech by the usual methods, or for the transmission of power, lies in generating an alternating current of rather high frequencies, modulating it in much the same manner as the output of a radio transmitter is modulated, and coupling the generator to the line. At the receiving end, apparatus is used which somewhat resembles a radio receiver. This is also coupled to the line and tuned to the frequency of the communication current.

The system of communication which results is known as "carrier current telephony," a name derived from the fact that the communication is carried by the high frequency source rather than directly, as in the case of the usual telephone line.

Since radiation is almost directly proportional to frequency and since the frequencies used for carrier current work are comparatively low, a line utilized for carrier current communication radiates very little energy, and communication is carried on primarily by conduction. Such transmission, therefore, is fundamentally different from transmission by radio.

Carrier current communication has advantages over wire telephony in addition to the fundamental in that it can be applied to existing lines. For example, it is customary for power companies who maintain long transmission lines to provide for telephone communication between their various stations and sub-stations, by running wires either above or below the power lines. Such procedure, while undoubtedly serving its purpose to a certain extent, is subject to failure from a number of sources.

For carrier current telephony over transmission lines, the exposure to such failure is appreciably reduced. The carrier current telephone equipment is coupled to the transmission line by means of a capacitance in one form or another. The maximum exposure offered in such installations is that of one or more coupling wires strung for a length of 1,000 ft. beneath the transmission line. This is necessary at both the transmitting and receiving station. The physical exposure, therefore, is reduced to a negligible minimum when compared to the total length of the line.

The reduced exposure of the carrier system also results in its far greater freedom from disturbances which are usually encountered in telephone lines erected adjacent to transmission lines. This refers to induced noises, lightning disturbances and atmospheric.

While carrier current telephony require for successful operation a closed alternating current circuit, such a circuit may be maintained under conditions which would be fatal to a direct current circuit. One or more of the conductors of a transmission line may be severed without destroying communication, since the alternating current circuit remains operative so long as there is a single conductor left intact, or so long as any opening in the line has sufficient capacity associated with it to keep the alternating current circuit intact.

Carrier current telephony, however, will not be successful on a system if the line is completely opened either by switches or by all of the conductors in the system becoming severed, unless additional so-called "coupling equipment" is provided for bridging the point at which the circuit is opened. This provision is most applicable at points where the circuit is intentionally opened at intervals such as at switching stations or at circuit breakers.

If communication is required by the two points under the most severe conditions, such as the power transmission line being down for a considerable distance, straight radio is the only sure solution. One of the greatest advantages of carrier current telephony, however, lies in the fact that it is not radio equipment and the stations are not radio stations, and that, therefore, it is not necessary to obtain an operating license from the Department of Commerce and keep an operator on watch at all times.

Carrier current telephony on power lines can best be justified when the system is erected. If carrier current is used, no provision need be made for the erection of telephone lines. Since such provision is a matter of considerable cost, particularly in cases where provision for a telephone line would mean the erection of towers several feet higher than would otherwise be required, it is far more economical to install a carrier current communication system.

Government's New Radio Regulations

FOR the benefit of all interested in radio broadcasting the following amendments to the radio regulations are reproduced as issued by the Department of Commerce recently:

To Radio Inspectors and Others Concerned:

Regulation 57, page 55, amended April 2, 1923, to read:

CLASS 2—Limited commercial stations are not open to public service, and are licensed for a specific commercial service or services defined in the license. Stations of this class must not transmit or accept public messages from other stations. No rates are authorized.

Licenses of this class are required for all transmitting radio stations used for broadcasting news, music, lectures, church services, government reports, and such matter, and do not permit the transmission of private or commercial communications.

The reading of telegrams or letters by broadcasting stations will not be construed as point-to-point communication so long as the signer is not addressed in person and so long as the text matter is of general interest.

Broadcasting stations must be operated by or under the supervision of an operator holding a commercial second-class license or higher; such operator must be on duty during the entire time the station is being operated.

No testing or experimenting is authorized in broadcasting stations between the hours of 10 a. m. and midnight, local standard time.

Broadcasting stations the operation of which interfere with the reception of time signals and meteorological information by marine service must remain silent while such signals are being transmitted.

Class "A" Radiotelephone Broadcasting Stations

Class "A" radiotelephone broadcasting station licenses will be issued to stations equipped to use power not exceeding 500 watts in the antenna, and will be assigned a wave length between 222 meters (1,350 kilocycles) and 300 meters (1,000 kilocycles).

Where more than one station of this class are licensed in the same city or locality a division of time will be required if necessary.

Class "B" Radiotelephone Broadcasting Stations

A license will not be issued for a station in this class which does not comply in every respect with the specifications hereunder.

Specifications covering the requirements governing the construction, licensing, operating and service of Class "B" radiotelephone broadcasting stations:

WAVE LENGTH—The wave lengths between 300 and 345, and 375 and 545 meters only will be assigned for the use of stations of this class, which must be free from harmonics. Whenever necessary the use of a coupled circuit transmitter will be required. Hereafter but one wave length within these ranges, including the 400 meters wave length, will be assigned to any one locality.

POWER—The power supply must be dependable and non-fluctuating. The minimum required will be 500 watts in the antenna and the maximum shall not exceed 1,000 watts in the antenna.

MODULATION—The system must be so arranged as to cause the generated radio-frequency current to vary accurately according to the sound impressed upon the microphone system.

SPARE PARTS—Sufficient tubes and other material must be readily available to insure continuity and reliability of the announced schedule of service.

ANTENNA—The antenna must be so constructed as to prevent swinging.

SIGNALING SYSTEM—Some adequate and dependable system must be provided for communication between the operating room and the studio.

STUDIO—The radio equipment in the studio must be limited to that essential for use in the room. The room shall be so arranged as to avoid sound reverberation and to exclude external and unnecessary noises.

PROGRAMS—The programs must be carefully supervised and maintained to insure satisfactory service to the public.

MUSIC—The use of mechanically operated musical instruments is prohibited.

DIVISION OF TIME—Where two or more stations of Class "B" are licensed in the same city or locality a division of time will be required if necessary.

Forfeiture of Class "B" Privilege

Licenses issued for the use of the wave lengths between 300 and 345 meters and 375 and 545 meters shall specifically provide that any failure to maintain the standards prescribed for such stations may result in the forfeiture of the Class "B" privilege and re-licensing of the station to use a wave length below 300 meters.

All radiotelephone broadcasting stations now licensed to use 360 meters (834 kilocycles) are placed in this class. No new licenses will be issued for stations to use this wave length. Renewal licenses for the use of 360 meters will be granted if necessary.

(Signed) D. B. CARSON,
Commissioner.

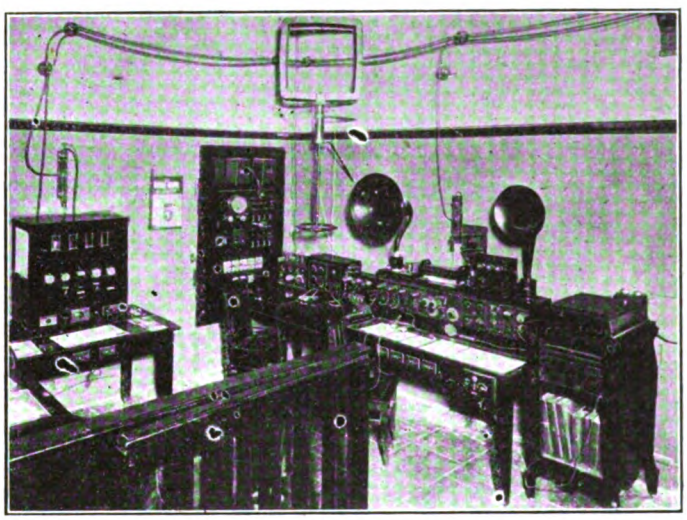
Approved:
(Signed) Herbert Hoover,
Secretary.

Combining Radio and Telephone

(C. Kadel and Herbert)

Many men, having found out how immensely important radio is in daily life, have installed radio receivers in their private offices, in order to get market prices first hand without waiting for ticker or paper reports. The particular office above is combining radio and the long-distance phone to circulate reports directly over the long-distance line between two offices of the same company.

A Cuban Broadcasting Station



(C. Kadel and Herbert)

Interior of the control and operating room of Station CG, Havana, Cuba. Of particular note is the complete and extremely powerful receiver, located on the table. Fans who think that they have a receiver when they use four or five tubes are invited to look at the 12 tubes used here, besides the power amplifier and additional two-stage radio-frequency when the loop shown in the corner is used. The transmitter control is directly next to the operator, and the transmitting apparatus is in the small case to the left of it.

Allocation of New Wave Lengths for Class B Stations

Wave Lengths for Specific Stations Will Be Assigned Later

THE Department of Commerce issued last week the allocation of wave lengths for class B radio broadcasting stations published below.

The specific wave lengths indicated are in accordance with the plan sent to radio inspectors following the recommendations of the Second National Radio Conference. The radio inspectors have been instructed to communicate the plan to stations in their districts. Every station which the department has so far heard from has willingly fallen in with the plan. Of course, it is understood that any station now operating on 360 meters has the privilege of remaining on that wave length.

It is to be noted that assignments are for cities and not for specific stations.

Wave lengths marked "Reserved" are being held for localities in the zones where Class B stations do not exist at the present time.

Entertaining Fifth Ave. Crowds

(C. Kadel and Herbert)

Blasé New Yorkers were recently startled out of their usual complacency when they heard music and talking in the vincinity of the Public Library, apparently emerging from nowhere in particular. Upon closer inspection, the curious found that Miss Tinsler had equipped a tea wagon with a De Forest reflex set and a couple of loud speakers, and was taking a stroll accompanied by sounds of sweet music from WEAF and WJZ. Miss Tinsler and her Radio Go-Cart in front of the Public Library are shown here.

Will the Freeman Tube Revolutionize Radio?

By Arthur S. Gordon

[The prophecy put forth by the writer of this article is, of course, conjecture; but it is based upon a conviction that the advent of a practical alternating current tube will bring a radio receiver to the stage where it can be connected with a household electric lighting fixture, as a vacuum cleaner or an electric iron is now attached. Does the Freeman tube hold this promise? Will it revolutionize radio? The writer presents the facts as he sees them—RADIO WORLD readers may draw their own conclusions. The Freeman tube, the author says, has been successfully tested and used with alternating current and the theory of its operation is sound. The writer has gone a step ahead and indicated the possible future of a tube with the characteristics of the Freeman device.—Editor, RADIO WORLD.]

WILL the vacuum tube newly evolved by Mr. H. M. Freeman revolutionize the radiophone industry? Radio engineers who have examined the features of this new tube say that it makes possible the dream of the vast radio public for a receiver which will operate by being connected to an electric lighting fixture, much as a lamp, or a flatiron, is connected now. No other outside helps will be needed excepting a "B" battery. The lighting wires will not only furnish the power with which to light the filament of the tube, but they will also furnish the aerial. A ground, it is thought, will not be necessary.

An extra element in the Freeman tube not found in the standard tube makes all this possible. The ordinary three-element tube contains a filament, a grid and a plate. The Freeman tube has a fourth element, consisting of a nickel tube, which entirely surrounds the filament, which in this case is made of ordinary tungsten. This nickel tube or sleeve is coated with electron-producing oxides, of barium and strontium, which, when heated to a proper temperature by the filament, give off the electrons for the operation of the tube. The filament is thus relieved of this duty, and is used only as a heater for the separate electron-producing element. Because the flow of electrons is not dependent upon the quality of the filament current, it is possible to light this filament with alternating current, without that persistent and annoying hum so noticeable when ordinary tubes are used in the lighting circuit.

A step-down transformer is used, of course, with an output of six volts as reduced from the input of 110 volts. The grid and plate are the same as in other tubes and perform the same functions. When used with the present regenerative circuit, the Freeman tube is connected up as shown in the accompanying hook-up. Note that the nickel sleeve over the filament is connected to the minus post of the "B" battery. This is so that it can carry out the work of the filament in its electron-producing function. Observe also that the filament is in a separate circuit and has no connection with the remainder of the set other than to heat the nickel sleeve.

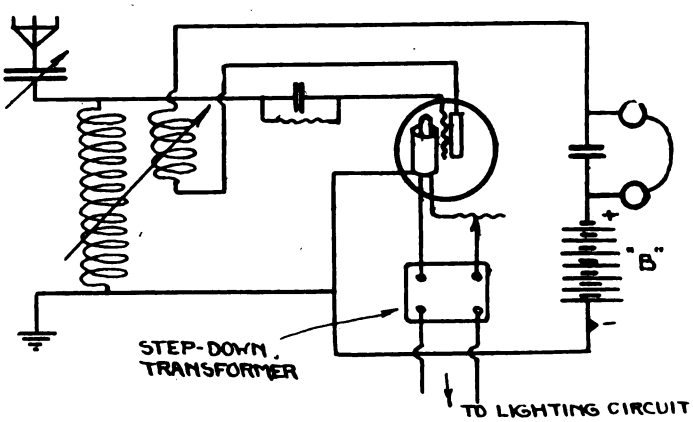

Diagram illustrating how the Freeman tube will be operated from commercial lighting circuits. A separate nickel-oxide-coated plate is heated by the filament. The nickel plate is depended upon for the electronic flow, instead of the filament, as is now the practice.

The Freeman tube is not yet on the market in commercial quantities. It is expected to capture the trade of the amateur from one end of the country to the other. It marks a distinct step in the evolution of the science.

Hints to Amateur Workmen from an Old Hand

STUDY your drawings with the greatest care. Learn to read them and understand just what they mean. This is the secret of rapid, efficient and satisfactory work. Be sure you understand both drawings and specifications before you touch a tool. An observance of this rule will not only save time but prevent the waste of material and temper.

"Order is Heaven's first law." Nature is the best example of the truth of this saying. Have a place for everything and keep everything in its place. This means not only tools, but material such as screws, nuts, bolts, connectors, binding-posts—in fact, all small parts.

Perform every task to the best of your ability—as if it were the only chance you would ever have to do this particular bit of work and do it right. "That's good enough" has no place in the good workman's vocabulary.

"It's a poor workman who complains of his tools." Many amateurs cannot afford a full set of tools and therefore are obliged sometimes to make one tool do the work of several. It is surprising how few tools are required.

Neatness and care in every operation performed will pay big dividends in results. Good work cannot be hurried even by a skilled mechanic. The principal advantage a professional workman has over the amateur is due to experience. After you have drilled as many holes as the man in the shop around the corner, you may be able to drill as many per hour as he; but if you take plenty of time, you can do each job now as well as he can.

Especial care should be exercised in making electrical connections and in following directions explicitly wherever they have to do with parts which transmit electric current. A half-soldered joint, a poor electrical contact or using too much flux when soldering will cause the failure of the best piece of electrical apparatus ever built.

When designing a panel, lay it out on paper first. This is a good way to save material—and disappointment.

Keep your tools sharp and clean. An oilstone, a rat-tail file and a three-cornered file are sufficient to keep your tools in first-class working order. All tools, especially those not in constant use, should be wiped at least once a week with an oily rag. This prevents rust—the sign of a careless workman.

Clean up the dirt and chips when you have finished work. This prevents a possible fire hazard, helps your standing with the family and gives a personal satisfaction such as can be enjoyed only by one who has learned to do things.

Latest Broadcasting Classifications and Regulations Issued

WASHINGTON, D. C.—Official orders from Secretary Hoover have gone forward to the nine radio districts directing each inspector to put new radio broadcasting classifications into effect immediately as far as is practical.

New regulations provide for the allocation of the nationally exclusive wave length to all Class B or high-powered broadcasting stations and the distribution of wave lengths within the band 222 to 300 meters in each district to the Class A stations before May 15. At noon on that date, general broadcasting on 400 meters will cease, the transfer to new wave lengths being made. Such Class A stations as desire to continue to broadcast on 360 meters may do so in the new class designated as C, but no new licenses will be issued on 360 meters.

Radio, Restless Mystery

By Will Chamberlain

I HAD not dreamed that quiet atmosphere
Screened lips of such surpassing song,
I had not known that love and hope and fear
From hearts afar could this same stillness throng.

I had not dreamed that oratoric pleas,
Peak-touching flights of forums otherwhere,
Could flash, as on a silver-pinioned breeze,
To me across the ocean waves of air.

But now I know, and knowing, pause to think.
O restless hand that picks from sky and cloud
The gems of mystery, and with them spaces link—
You have high fellowship with God!

Stations now listed in Class A which can qualify in Class B, may be transferred upon application to local inspectors. No new licenses will be issued until all old stations receive their new waves, although several applications are on file at the department.

Hereafter all Government reports will be sent out on wave lengths assigned to the station and the exclusive use of the 485 meters wave length will be discontinued for this service.

The thirty Class B stations, all now operating on 400 meters, will virtually become national broadcasters, since with exclusive waves they should reach every corner of the country. To-day 15 states and 21 cities have B stations. In seven localities more than one station exists. This is true in Philadelphia which has four stations, and also in New York, Atlanta, Kansas City, Detroit, San Francisco and Los Angeles each of which has two. In these cities time will have to be divided as is done to-day on 400 meters. Philadelphia, New York, San Francisco and Los Angeles, however, will share four additional wave lengths it is understood.

Specific wave lengths have not been announced by Secretary Hoover collectively, but it is understood that each radio inspector will announce those in his district as soon as they are assigned.

Several wave lengths have been reserved for such new stations as may qualify or transfer from Class A. It is believed that Arlington, NAA, will change from 710 meters to a commercial wave of 435, and that when the new R C A station at Washington is licensed, it will receive an independent wave, since NAA is busy almost continually. Special waves will probably be given also to the new General Electric Company stations planned, one near San Francisco and one between Schenectady and the Pacific Coast, both of which will be high-powered stations.

In a letter to all inspectors, Secretary Hoover points out that all broadcasters must stick to the new individual waves if interference is to be eliminated. His instructions follow:

"Under the reallocation of the wave lengths plan, effective May 15, 1923, it will be necessary for all transmitting radio stations to be accurately adjusted to the wave length specified in the license.

"Any variation from this rule may be considered a violation of Section 2, Act of August 13, 1912, justifying the revocation or suspension of the station license.

"Beginning May 15 radio inspectors of each district will carefully check the transmitting wave lengths of stations in their districts by personal inspection of the stations as far as practicable and by listening in with accurately calibrated receivers, and report to the department promptly any discrepancies observed.

"The Bureau of Standards will transmit standard wave lengths from time to time, which will be helpful in determining accurate wave lengths, and will also listen in and check the wave lengths being used."

Dr. De Forest's "Speaking Flame" Eliminates Vibrating Diaphragm

DR. LEE DE FOREST announces that he has realized the dream long held by telephone engineers, namely, the translating of sound waves in the air directly into electrical currents, thereby eliminating the vibrating diaphragm.

An entirely new form of microphonic device has been evolved by the inventor. It is a "speaking flame," which gives promise of revolutionizing the present methods of transmitting voice sound waves into electrical waves and without the distortion associated with the older methods of voice transmission. The field of immediate application of the talking flame device is not only in the province of the talking motion picture film, but in the world of radio as well, and especially in those stations used for broadcasting the human voice.

"In response to numberless inquiries of scientists, educators, engineers and others directly interested in the development of the talking motion picture art," says Dr. de Forest in a statement issued by the De Forest Laboratories, "I should like to take this occasion to announce that as a result of my development of the new phonofilm my investigations and experiments have resulted in revealing what I consider will be another revolutionary step forward in the transmission of the human voice or sound through space. The advance itself may be regarded as a technical one from the engineering point of view, and yet from the benefits to be derived from the world at large the improvement is somewhat marvelous in that by means of it hereafter we shall be enabled to change voice or sound waves directly into electrical energy.

"It has for a long time been realized by telephone and acoustic engineers that the necessity for a diaphragm at the transmitter introduces at the very outset of the sound translation problem a source of distortion and imperfection. It is the diaphragm more than any one element which introduces the deformation in recording and in reproducing voice and music on the phonograph as well as in telephone transmission. Therefore, for many years efforts of telephone and phonograph engineers have been devoted to reducing as far as possible distortions thus introduced by the natural period of vibration of the diaphragm, or membrane, against which the sound waves impinge.

"But where exact and accurate translation of sound waves into electric currents is desired it is quite unnecessary to use a vibrating diaphragm. The discovery of the audion first came to me as a result of observation of a sensitive gas flame. From this rudimentary idea, which originated in 1900, was developed, during the ensuing five years, the three-electrode vacuum tube which was destined to become the telephone repeater or amplifier for which telephone engineers had been vainly searching for twenty years.

"And now in exactly the same way has been evolved a new form of microphonic device, which turns sound waves in the air directly into electric currents. Take the ordinary bat-wing gas burner or a certain form of Welsbach mantle gas light, or special forms of oxy-acetylene gas flames, insert two heat-resisting electrodes therein, in proper relation to the flame and to each other, connect these electrodes to an appropriate electro-motive force. You will then have an extremely sensitive sound converter which gives an electric reproduction of the sound waves in the air enveloping the flame which is of an entirely different order of fidelity from that ever obtained from any form of microphonic device, using a diaphragm, whether this be of the carbon, electro-magnetic, or electro-static variety.

"But I have found still another method of translating sound waves direct into electric currents without the imposition of any diaphragm. This arrangement, independently suggested to me by Mr. Theodore W. Case, is the reversal of the well known 'thermophone,' a device wherein an extremely fine platinum wire, through which is passed telephonic currents, reproduces these in the form of sound waves due to the alternate heating and cooling of the air immediately surrounding the extremely fine wire."

(C. P. & A. Photos)

Dr. Lee De Forest and his "speaking flame" device.

An Aerial Problem to Solve

BELOW, fellow fans, is a problem and a common one in these days; but this specific instance makes it stand out above all others of its kind.

On top of a certain apartment house in New York City, there are located no less than 23 aerials, of all shapes, sizes and form, some of them running just a few inches above the others and forming a veritable cage of wires. The roof of the house is large and there is plenty of space to put them up. The trouble is not in the erecting of the antenna, or anything of that sort. It is that out of the 23 there is only one that is not a regenerative set, and that is a humble crystal set, which due to re-radiation does nearly as good work as the one-tube sets in the house.

The trouble is that of the 22 other owners, there is not one who can properly tune in a station, even though it be WJZ, without squeals and howls, not only in his set but in the sets of all those around him. It is impossible to listen to DX work before 1 a. m. because up to that time all the other sets are persistently squealing and howling into one another's ears, and making the air sound like a pig sty when there is a particular fight going on.

The problem is how can this be eliminated, and at the same time give satisfaction to the owners of the sets?

Don't say "Cut out the regenerative sets," because they are all expensive and up to date.

Radio and the Woman

By Crystal D. Tector

WELL, well, I certainly woke up a lot of my women readers when I published the request to send in DX notices. I have not the space to publish them all, but here's the best one, from Mary Devoux, way out in Sacramento, California. She writes me a nice little letter and tells me that she hears the following stations regularly on her brother's two tube set, which was made in the cellar of the house. Her farthest distances are Davenport, Iowa, station WOC, and Fort Worth, Texas, WBAP with the following in-between stations: KDYY, Denver, Colo.; KDYL, Salt Lake, Utah; KDYW, Phoenix, Ariz.; KYJ, Los Angeles, Cal. Now girls, don't be backward about coming forward, as when I get enough "lady DX'rs" I am going to ask the editor to run a Lady DX page and publish all the reports of the girls who read RADIO WORLD and listen in.

* * *

We were invited to a birthday party in Brooklyn last Sunday. At about 8 o'clock the guests filed into the parlor and were agreeably surprised at the sight of a beautiful radio set of ample proportions. In a few minutes we heard the strains of a popular dance tune and of course the crowd lost no time getting coupled up for the light fantastic. Needless to say, the party was an unquestionable success and we have an inkling that this crowd one and all will find an excuse to visit the apartment of Mr. and Mrs. B. very soon again.

* * *

French-speaking residents of Canada are learning English from the announcers of WGY, according to a letter received recently by the Schenectady radio broadcasting station of the General Electric Company. Mrs. R. Normandin, a resident of Shawinigan Falls, Quebec, writes: "Many persons are taking advantage to learn to pronounce English, especially from your station. Our daughter, aged four, speaks French only, and she startled us recently when she said all of a sudden "WGY, Schenectady, N. Y., one minute please." Those in charge of the radio broadcasting activities of the General Electric Company realize that the right to broadcast carries with it the responsibility to offer something worth while. An earnest and conscientious effort is made to provide good music, to give variety of entertainment and to give helpful addresses. Announcers strive to pronounce all words correctly. Before an announcement is made or an address delivered, the announcer goes over the manuscript, and if he is in doubt about the pronunciation of a word he looks it up. The announcer knows that his audience is made up of those who may copy his pronunciation and those who may criticise the slightest slip. He therefore has two reasons for accuracy.

* * *

A friend of ours who started in to study the code over the radio has become quite proficient, and can now copy the amateurs around town, with the exception of one station that sends fast no matter who he is talking to. He must use what they call a "bug" key because he certainly is a "bug." When it comes to sending he sounds like a Ford when a woman is driving it up hill and can't keep her foot on the gas steady. Slow—fast—stop—slower, fast—faster—all balled up—repeat—then he waits and has to repeat it because no one can understand him. Wish he would learn how to send. I live just two blocks away from him and like to listen to the "hams" once in a while, but he simply spoils all my aspirations to copy them. I think a good idea for some of those speed hounds would be to tame themselves down until they send distinguishable copy and then pick up speed gradually.

Radiograms

The electric central stations of the United States are planning extensions and additions in 1923 which will cost more than six hundred million dollars.

* * *

Marion Davies, the movie actress, thinks that radio will eventually be used to acquaint people all over the country with events of importance transpiring in the motion picture world.

* * *

Dance music will be broadcast by WGY, the Schenectady radio station of the General Electric Company, every Saturday evening from 9 to 11 o'clock for a period of about six weeks. The music will be supplied by Cain's Castle orchestra. The WGY studio will be connected to the dance hall by wire.

* * *

A letter signed "Patients of the Vermont Sanatorium" was recently received by WGY, the General Electric Company broadcasting station at Schenectady, N. Y., acknowledging the pleasure and entertainment they get from the radio programs. The sixty patients are suffering from incipient tuberculosis and most of them depend upon WGY for the Sunday religious services. They wrote that they get the 7:45 p. m. concert, but have to be tucked into bed at 8:30.

* * *

Frank Smithson, the stage director, has been at work on a plan for radio entertainment on behalf of the Wired Wireless Corporation, a subsidiary of the North American Company, which Smith calls the "Theatrome," coined from "theatre-at-home." The Wired Wireless company is installing a large number of receiving sets on Staten Island, New York, to test its system of wired entertainment, before attacking the metropolis. This demonstration will test the practicability of General Squier's devices for receiving music and entertainment over the regular house lighting electric system.

The chemical faculty of the University of Chicago is soon to broadcast chemical lectures by radio.

* * *

Construction of a radio station, claimed to be the second largest in the country, has been started at Hialeah, near Miami, Fla., by the Tropical Radio Telegraph Company. The plant is to handle South American, Central American and West Indian business and will cost about $250,000. The towers will be 437 feet high with a span of 1,500 feet.

* * *

All London is in the throes of wireless telephony, according to W. E. Wroe, of San Antonio, Texas, who arrived last week in New York after a long stay in England. One of the novel uses to which the new marvel has been put is the radio sandwich man, who parades up and down the Strand and Piccadilly with a complete radio outfit. He is able to pick up all the stations, and all passers-by get an earful.

* * *

From Georgian Bay, Canada, WGY, Schenectady, N. Y., has received one of those letters which help radio station personnel and artists feel that their efforts are relieving the sum total of loneliness in the world. L. E. Monck, on Wahsoune Island, Sans Souci, Ontario, Canada, writes: "We are all very much attached to the program of WGY, and, best of all, the night devoted to the WGY players, as this class of entertainment takes us back to the cities and bright lights, and for the duration of the play we forget we are alone on one of the 30,000 islands of Georgian Bay, and, for weeks at a time, cut off from all communication with the rest of the world. Our nearest winter post-office is Parry Sound, eighteen miles away; and when the ice is too thick to use a boat and not thick enough to walk on we just stay here and hope for good ice so as to be able to get out, either with dog-team or horse, to get our mail. Just now the ice is good, and we make the trip every eight or ten days, but soon now the ice will start to break up, and then we are marooned until it is clear enough for a motor-boat."

Elementary Instruction for the New Army of Radio Beginners

Constantly Used Terms Explained in Simple Language for the New Radio Enthusiast

By Lynn Brooks

RADIO: The transmission and reception of signals or vocal sounds through the ether, without the use of conducting wires, by means of high frequency electric waves. In radio telephony, these waves are modulated by means of suitable transformers, the speaker talking into a microphone, where the propagated waves are modulated to conform to the variations of the human voice. In radio telegraphy the propagated wave is formed by means of a spark jumping across a space.

* * *

AERIAL (antenna): A system of wires used to collect energy transmitted through space. They are divided into different types, such as inverted L, T, and fan, each getting its name from its appearance. The L antenna, or aerial, is constructed so that the lead-in is taken off one end, generally the end nearest the apparatus. The T aerial is constructed so that the lead-in comes off the center, giving the appearance of an enlarged letter T. The fan antenna is constructed so that the wires radiate, after the manner of the leaves of a fan, spreading from a central pole with the lead-in taken off the converging point of all the wires.

* * *

GROUND: A means of dissipating the received energy after it has done its useful work in going through the circuit. It generally consists of a wire attached to a cold water pipe, or a pipe driven into the earth. The ground wire should not be any smaller in diameter than the sum total of diameters of the wires used in the antenna where a transmitter is concerned; but for receiving, it may be a single wire about No. 12 or 14 in size.

* * *

INDUCTANCE COIL (tuner): A number of wires wound on a suitable core, such as a round tube. They can also be made in various other forms, such as honeycomb coils, spider web coils, pancake coils. In the first, the straight inductance coil, the wire is wound contiguously in one single layer. This has been found to be quite inefficient, because such a coil possesses "distributed capacity," or capacity between one turn and its neighbor, with the insulation of the wires acting as the insulating plate. The honeycomb coils are wound in such a manner that all the turns are spaced, and in winding they cross one another at an angle. Such a coil can be built up to very high inductance values, taking but little space, and having a very low distributed capacity. Spider web coils are wound on a "former" resembling the spokes of a wheel, the wire weaving in and out. In the pancake coil the wire is wound spiral-wise, one layer on top of the other, in the form of a continuous spiral.

* * *

FIXED INDUCTANCE: A coil, the inductance of which cannot be varied. Honeycomb coils and spider web coils come under this classification.

VARIABLE INDUCTANCE: A coil, the inductance of which can be varied through the agency of either taps or sliders.

* * *

NON-INDUCTIVE RELATION: Coils placed in such a manner that a current passing through one will not induce a similar current in the other. This can be done by placing the planes of the coils at right angles to each other.

* * *

CRYSTAL DETECTOR: A rectifier of the received radio-frequency signals which makes them audible in the phones. As the received signals are alternating current, they would not make any impression on the diaphragms of phones. The crystal in the detector allows only one-half of the current cycle to pass. It is by nature a unilaterial conductor and allows the current to pass in only one direction, making a direct current out of the pulsating or alternating current. Without some means of rectification, the signals could not be made audible.

English Boy Wins First Prize

(C. Kadel and Herbert)
Master W. H. Hildersley, 15-year-old radio enthusiast, was awarded first prize at the Handicraft Exhibition, London, England, for making the best one-valve crystal combination radio set. The entire set was made by himself, with the exception of the tube and phones, and he has heard American phone stations in London on it. The illustration shows a local official listening in to American concerts on this home-made combination receiver.

TYPES OF CRYSTAL DETECTORS: Crystal detectors are of several different kinds, such as galena, carborundum, silicon, pyrites and numerous other minerals, some of which are elements. Others are synthetic, being products of the electric furnace or chemical reaction. Galena, the most popular, is sulphide of lead. It is bluish grey in color. Carborundum, which is a product of the electric furnace, is irridescent, the basic colors being purple and green. Silicon, which is an abundant element, is light steel grey in color and extremely hard. Silicon is also made in the electric furnace, by fusing silica with a small amount of pure carbon at extremely high heat. Pyrites is found in several forms, two of the most common used in radio work being iron pyrites (commonly called fool's gold) and copper pyrites (chalcopyrites). The first is a dull gold color and copper pyrites is dull brown or almost black in color. These last two are mostly used in connection with some other mineral to make a "perikon" detector, which is very sensitive. These minerals are among the most common in use.

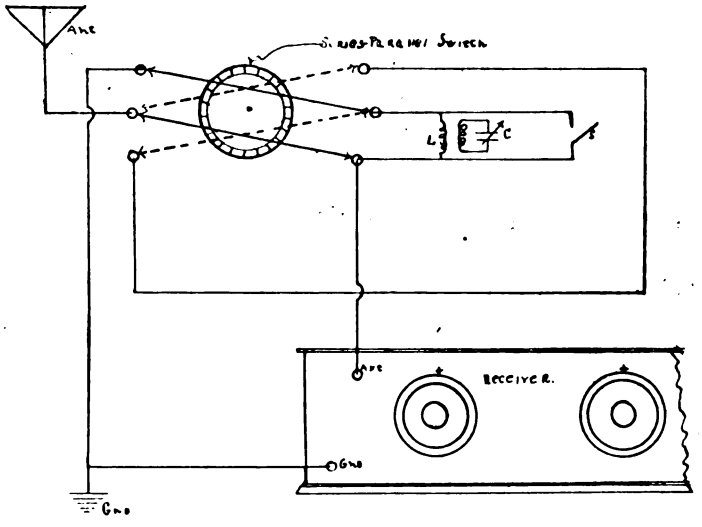
An Improved Wave Trap Filter

By C. White, Consulting Engineer

THE number of broadcasting stations is steadily increasing. If some method is not devised to secure greater selectivity within the wave bands that have been assigned for general broadcasting and amateur work, it will become extremely difficult for any one to get the station he wants without much interference. Especially is it true in the more densely settled cities, where it is now possible to hear two stations at the same time with a receiver that tunes rather broad. Although the solution of the problem is the construction and design of more selective receivers and circuits, still there are many who are perfectly satisfied with their outfits save for the lack of proper selectivity. The ordinary crystal detector outfit and the single circuit regenerative receivers, indeed, have been rather hard hit for selectivity in large and densely populated districts.

Then, again, there are many owners of radio-frequency amplifiers who are desirous of increasing the selectivity of their receivers, in order to cut out the local stations that are not desired when distant ones are trying to be tuned in. The wave trap filter is the logical solution of the problem.



How to hook up a wave trap filter with a series-parallel switch to obtain great selectivity.

A wave trap filter simply adds to the selectivity of the tuning circuit that is already on the receiver and, while it slightly cuts down the volume of the received signal, it certainly adds to the clarity by removing interference. The warm weather radio pest is greatly cut down by the use of filters, and it is possible to receive under many conditions with filters when ordinarily such a feat would require a more selective tuner with more amplification.

The filter illustrated is nothing more than a tuned coupled circuit. The inductance coil L and the variable air condenser C form the desired filter. The coil L can either be wound on a four-inch tube with 50 turns of number 22 D.C.C. magnet wire with a rotor having 40 turns, or a standard type of variocoupler can be used, employing the stator in the main circuit and the rotor in parallel with the condenser C. The latter is preferable since by changing taps on the stator and the coupling, the sharpness of the trap tuning subsequently can be readily altered in order to meet the requirements of the interference. The condenser C has a maximum capacity of .0005 micro-farads, which is the normal capacity of the average 23 plate air variable. The switch S is nothing more than a single knife-blade switch that is used to short out the filter while tuning in on the receiver. Under normal conditions of operations, S is kept open as illustrated. A series-parallel switch enables the filtering element to be thrown in series with the ground-antennae terminals of the receiver or parallel with these terminals, depending upon the nature of the interference that it is desired to eliminate. The series-parallel switch consists of six switch points and two switch arms which are rigidly attached to a knob. By moving the knob so that the switch arms take the position indicated by the dash lines, the wave trap is placed in series with the receiver and, by allowing them to remain in the position as shown by the solid lines, the wave trap is placed in parallel with the receiver. The ingenious amateur can mount his filter with the control switches in a little cabinet or incorporate it in the cabinet with his receiver if there is enough room inside and on the panel.

The operation of the wave trap is very simple. If it is desired to erase an interfering signal from a nearby station the blades of the series parallel switch should be so placed that the filter is put in series with the receiver. The switch S is closed and the desired station is tuned in; then S is opened and the condenser C and the coupling is adjusted until the interference is eliminated entirely or reduced to a minimum. Under certain conditions when the strength of the interfering signal is so strong that it is impossible to tune in the desired station on the receiver first, then it would be better to close S, tune in the interfering signal on the receiver, open S and move C and the coupling until the volume of the interference is a minimum. After this has been accomplished the receiver can be tuned to the wave length of the desired signal. Often it is wished to tune in one particular station when many other stations are interfering. Under such conditions we want to pick out one station from the midst of many who are operating around the same wave length, instead of eliminating one strong interfering station as explained previously. In this case the wave trap is placed in series with the antennae-ground terminals of the receiver by means of the series-parallel switch and short-circuiting switch S is closed. Again the receiver is approximately tuned to the signal of the desired station, S is opened and the series-parallel switch is then moved so that the filter is placed in parallel with the receiver. Then C and the coupling is adjusted until the signal desired is amplified to a maximum and the volume of those interfering will be greatly reduced or completely fall out of audibility. In the first place L and C were tuned to the wave length of the interfering station and, in the second, L and C were adjusted to the wave length of the desired station.

There is probably no small addition to your receiver which would be more useful and more fully appreciated than a filtering wave trap such as briefly outlined. With the use of this device a single circuit set is made almost equally as selective as the triple circuit regenerative receiver, which is generally considered paramount among amateur radio receivers for selectivity. There is generally just enough difference in wave length between the various broadcasting and amateur CW stations to allow the filter to function satisfactorily. Users of multiple stage radio-frequency amplification, which employs the standard type of radio-frequency transformers, have long been complaining of the poor selectivity they have been getting. While it was quite true that they could bring in the distant fellows, still their poor selectivity resulted in hearing many stations at the same time. The wave trap filter greatly aids to increase the tuning selectivity and by its use the owners of radio-frequency outfits can obtain better results.

How to Make a Compact Universal Receiver

By W. S. Thompson, E.E.

IN designing the set described in this article, the author has tried to meet several specifications which are the outgrowth of the popular demand for a simple and compact receiving set that is really efficient and which can be constructed for a reasonable sum.

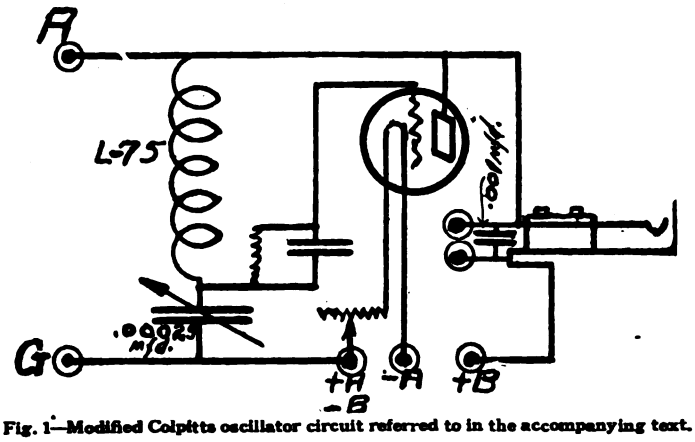

Fig. 1—Modified Colpitts oscillator circuit referred to in the accompanying text.

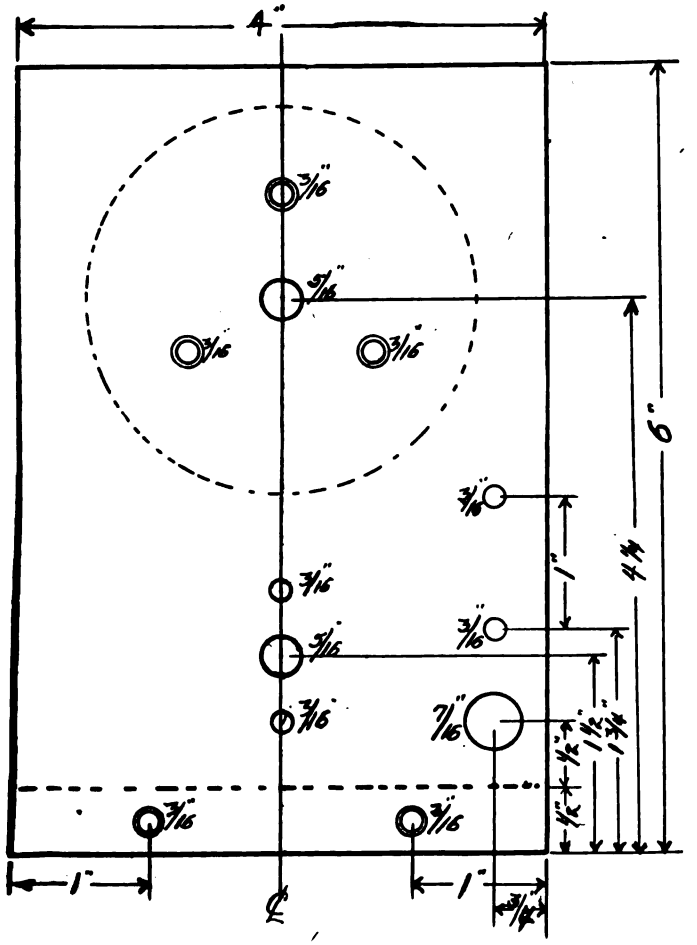

Fig. 2—Panel pattern used in making a compact universal receiver.

The electrical circuit which adapts itself very well to meet these specifications is the Colpitts oscillator, a modification of which is shown in Fig. 1. By using this circuit, regeneration has been incorporated although no additional control has been necessary, due to the fact that the regeneration can be controlled by the filament rheostat. The only tuning control that is necessary is a condenser, so the set as described can be very efficiently operated by the most inexperienced novice.

To eliminate all dead end losses and to make the set universal in its wave length range, a honeycomb coil with a standard mounting has been used for the inductance coil. In order to tune in to a higher wave length all that is necessary is to plug in a honeycomb coil with a sufficient number of turns to reach the desired wave length. The proper size coil to use can be obtained from the table published by the manufacturers of these coils. By calibrating the condenser dial for a number of different coils, a wave meter can be made of this set, the calibration holding true within a few per cent. for any antennae to which the set may be connected.

The author advises using a vaccum tube such as the WD-11, UV-199 or others of the same type, because a dry cell can then be used for the "A" battery, saving a considerable amount when purchasing the accessories and also saving considerable in the up-keep expenses. These dry cell tubes will be found to be ideal for use as a detector, especially when used in circuits in which regeneration is used.

Body capacity effects can be very easily avoided by connecting the rotating blades of the condenser to the ground binding post. By thus keeping the shaft of the rotor at ground potential, shielding by other means becomes unnecessary. Provision for connecting this set to an amplifying unit has been made by placing two binding posts on the panel. These binding posts should be connected in parallel with the jack as shown in Fig. 1. The jack used should be the special radio jack recently placed on the market, because it only extends back of the panel about an inch and allows the vacuum tube socket to be placed as near the panel as possible, thus conserving space.

The parts necessary for the construction of this set are listed below with average prices for each although the builder will probably be able to purchase them for less if he is a careful buyer:

Materials for Construction

1 Honeycomb Coil (75 turns)	$1.50	
I Variable Air Condenser (vernier) .0004 mfd.	2.50	
1 Filament Rheostat (vernier)	1.85	
1 Phone Condenser .001 mfd.	.40	
1 Grid Condenser with Variable Grid Leak	1.00	
1 Vacuum Tube Socket	.75	
1 Single Circuit Telephone Jack	.75	
1 Bakelite Panel 6"x4"x3/16"	.75	
1 Wood Baseboard 5"x4"x½"	.10	
5 Binding Posts	.25	
Wire for connections	.10	
Total Cost		$9.95

Accessories.

1 Dry Cell for Filament Lighting	.40	
1 B Battery	2.00	
1 Vacuum Tube (dry cell type)	6.50	
Total Cost		8.90
Cost of set with accessories		$18.85

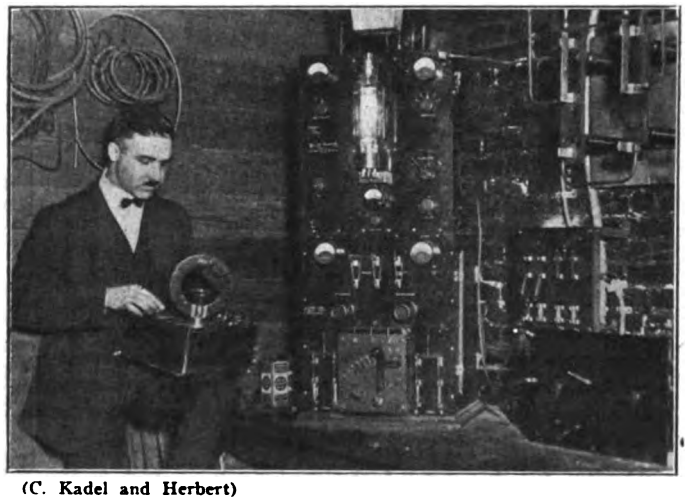
Testing a Church Broadcasting Station



(C. Kadel and Herbert)
Testing a broadcasting station for wave length.

That the recent popularity of radio broadcasting has left its mark on the churches of the country is testified to by the great number of churches which have adopted this method of spreading their services.

The latest addition to this growing list of stations recently made its debut under the call of WSAP. It is located in the basement of the church at 120th street and Lenox avenue, one of the more congested sections of New York City. It is, as shown in the illustration, a complete station in itself and does not rely on the retransmission of signals over land wires. The exact wattage of this particular set has not yet been determined, as it is only recently that it was installed.

It will operate on 360 meters wave length. The accompanying illustration shows Mr. E. H. Lee, United States Radio Inspector, testing the transmitter for wave length. Nothing is taken for granted in these days of radio congestion, so the radio inspector is a pretty busy man checking, rechecking and testing.

(Continued from preceding page)

After all the materials have been purchased, the builder should prepare the panel for mounting the apparatus by squaring off the corners with a file and drilling holes as shown in Fig. 2. The dimensions given can of course only be approximated for they will depend upon the make

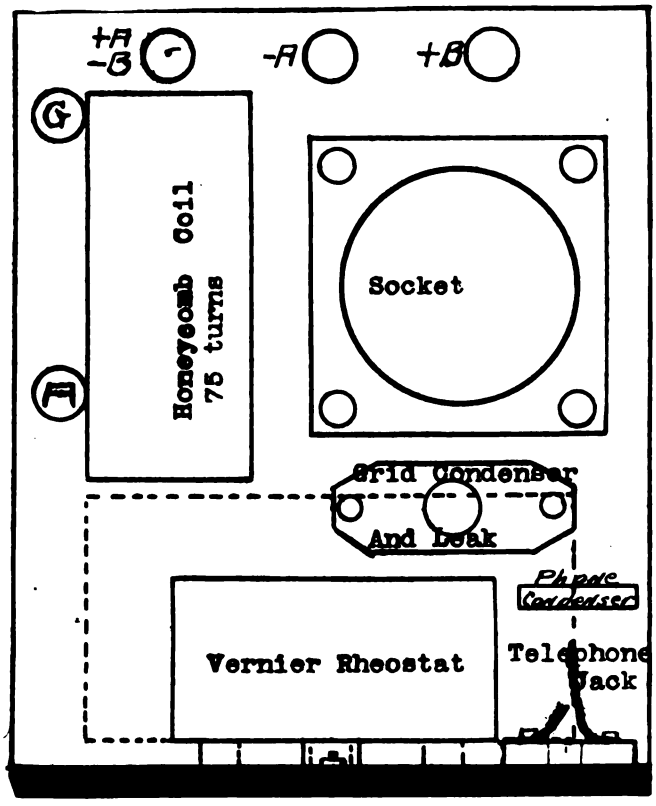


Fig. 3. Efficient arrangement of instruments on the baseboard of a compact universal receiver.

of the instruments purchased, so when marking the panel for drilling, the reader should be sure that holes for mounting screws are in the correct positions relative to each other. After all the holes have been drilled and those marked with double circles countersunk for flat head screws, the panel may be given a dull finish by rubbing it lengthwise with fine sandpaper until it is smooth. Repeating this process using a light machine oil and the sandpaper and then drying with a piece of cheesecloth, will give the panel a dull, permanent finish. The condenser, rheostat, jack and binding posts should be mounted on the panel following which the socket, honeycomb coil, grid condenser and binding posts should be mounted on the baseboard as shown in Fig. 3. The dotted lines in this figure show the outline of the condenser when the panel is fastened to the baseboard, care being taken that the socket and coil do not interfere with the condenser.

After having completed the assembly, the builder should wire the set using a heavy copper wire about No. 18 and soldering all connections. Connections to the various binding posts are shown in Fig. 1, binding posts being marked by small circles and lettered corresponding to binding posts marked in Fig. 3. The phone condenser can be mounted directly behind the telephone jack or between the two binding posts, provided for connecting the set to an amplifying unit. The phone condenser does not need any special mounting, being supported by the connecting wires which should be soldered to the terminals. When purchasing the phone condenser, the builder should be sure that the condenser has mica for the dielectric, and that its capacity will not change with change of atmospheric conditions. This can only be assured when the condenser has its plates firmly held together by a casing.

Before placing the tube in the socket and connecting the batteries it would be well to go over all the connections very carefully checking each one. This checking will often save a tube from being burnt out by excessive voltage, due to a misplaced "B" battery connection.

To place the set in operation, connect both batteries, ground and antennae to the correct binding posts and insert the tube turning up the filament rheostat until the filament is at its proper brilliancy. The tuning condenser should then be turned until some station is heard, the signal strength being regulated by the filament rheostat. If the rheostat is turned too far, the tube will oscillate, which will make the signals distorted if they are coming from a broadcasting station. A proper adjustment for the condenser and the rheostat will bring the station in loud and clear. After having found the combination which will give the best results, the value of the grid leak should be changed noting any improvement or any decrease in signal strength. The correct setting for the grid leak once found, will not have to be changed for a given tube, and hence it is not absolutely necessary to have a variable grid leak. The common type of pencil mark will work well after once determining the correct width and length for the mark. As this set is a so-called single circuit tuner the selectivity will not equal that of a set having coupled circuits, but if a short, low antennae is used, this fault can be remedied to a great extent. For receiving distant stations, this set will compare with any single tube regenerative receiver.

Method of Neutralizing Capacity Coupling

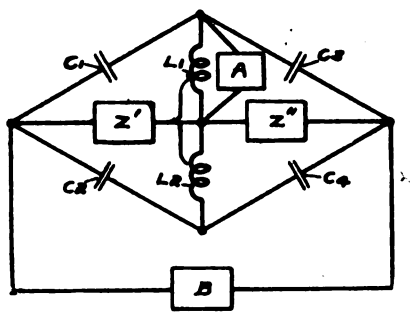
No. 1,450,080: Patented March 27, 1923. Patentee: Louis A. Hazeltine, Hoboken, N. J.

IT has long been known from practical experience that the presence of capacity coupling between the primary and secondary circuits of a radio receiver results in the transmitting of undesired signal oscillations, particularly those of short wave length, from the primary to the secondary circuit. This reduces the selectivity of the receiver and frequently prevents the reception of the desired signal, which is drowned out by a more powerful signal of a different wavelength. Two methods have been used to reduce the capacity coupling: first, the physical separation of the two circuits by as great a distance as is feasible; and, second, the partial enclosing of the circuits in metal screens. Neither method is entirely effective, for the first would require an impracticably wide separation of the circuits; while in the second the metal screens could not completely enclose the circuits as they would then prevent the desired magnetic coupling.

Again, it is well known that capacity coupling between the grid and plate circuits of an audion may result in the production of oscillations. Such oscillations are frequently very undesirable, particularly in audion amplifiers, as they may completely mask the signal which it is desired to amplify.

As a third example of the undesirable effects of capacity coupling, it has been found difficult to arrange a Wheatstone bridge for high-frequency measurements, due to the capacity coupling between the supply circuit and the detector circuit, which may result in a false balance and so vitiate the results of the measurements.

This invention is directed to the elimination of the undesirable effects of capacity coupling between two circuits such as are described in the foregoing examples. This is accomplished briefly as follows: An auxiliary circuit is provided which is electromagnetically coupled to one of the two original circuits which we will call the first circuit, and capacitively coupled to the other, or second circuit. If a disturbing voltage then exists in the second circuit, it will cause currents to flow both in the first circuit and in the auxiliary circuit, due to the capacity couplings. The electro-magnetic coupling between the auxiliary circuit and the first circuit is then arranged so that the magnetic effects of these two currents will neutralize



Professor Hazeltine's method of neutralizing capacity coupling by means of a special capacity neutralizer and balancing circuit. The principle is applied to his latest circuit to avoid oscillations.

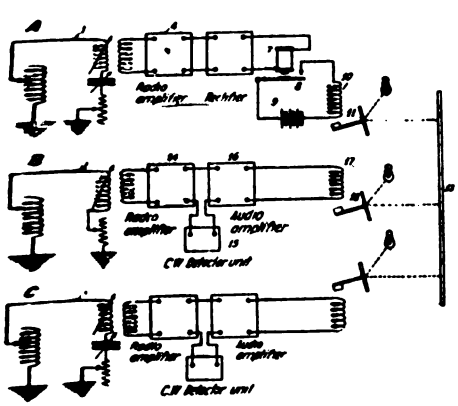
one another and so will result in no voltage across the first circuit. Conversely, if a disturbing voltage exists in the first circuit, it will result in no voltage across the second circuit, by the well known reciprocal properties of electric circuits.

The arrangement of the auxiliary circuit will depend on the forms of the original circuits. In some cases it is necessary to add coils or capacities to the original circuits to provide the required couplings, while in other cases the couplings may be obtained from coils present for other purposes or from inherent capacities.

Method and Means of Receiving Signals

No. 1,449,911: Patented March 27, 1923. Patentee: R. H. Ranger, Brooklyn, N. Y.

THIS invention relates to methods and means of receiving signals, and is more particularly useful in connection with wireless telegraphy, though it is not limited thereto.



Method of reception of radio signals to eliminate atmospherics and interference.

It is well known that atmospheric disturbances, commonly called "static," interfere with reception of radio telegrams, as the currents generated in the receiving systems by such disturbances blend with the signal currents and render the message more or less indistinct and, quite frequently, wholly unintelligible. There have been many attempts to overcome the effect of these disturbances, and, while some of these have been more or less successful, nevertheless there are times when static disturbances seriously affect the reception of radio messages.

My invention relates to the combination of several receivers, all working on the same signal, but each receiver having some essentially different characteristic such as in respect to directional properties, different location, damping, type of detector, type of receiver, etc.

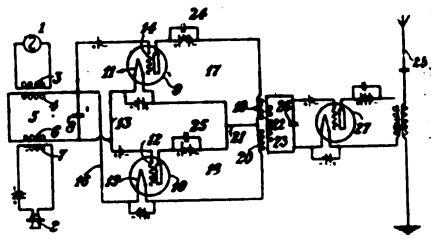
The messages received through the several systems are either recorded separately, and later placed adjacent to each other for the operator to interpret, or they are relayed to a central station and simultaneously recorded on the same strip of paper.

When the messages from the plurality of systems have been recorded it will be found in nearly all cases that the static obliterating a portion of a message received at one station is entirely absent in the message received at one or more of the others or else is of such character or magnitude that this portion of the message can be distinctly read.

Signaling with High-Frequency Waves

No. 1,449,382: Patented March 27, 1923. Patentee: John R. Carson, New York, N. Y.

THIS invention relates to a signaling system wherein signals are transmitted by means of a modulated high frequency carrier wave, and more particularly it relates to a wireless telephone system. Its objects are: (1) to provide a transmitting system whose characteristic is such that the transmission or radiation of energy is automatically prevented except during the time when signals are actually being transmitted and the transmission or radiation of the unmodulated carrier wave is at all times prevented; (2) to provide novel tuning adjustments at both receiving and transmitting



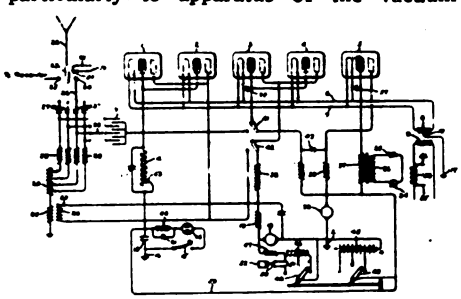
Employing vacuum tubes to modulate the high frequency produced by other vacuum tubes so as to obtain perfect modulation and transmission.

stations; (3) to provide means at the receiving station whereby both the quality and intensity of the received speech is improved as well as the selectivity of the receiving system; (4) to provide arrangements for the duplex transmission of signals; and (5) to provide a duplex translating arrangement comprising individual paths and a common path so associated with an outgoing circuit and two incoming circuits comprising sources of electrical variations, that said outgoing and incoming circuits will be independent of each other, and oscillations from one of said sources will only be transmitted through the translating arrangement to the outgoing circuit when the other source is active.

High-Frequency Signaling System

No. 1,449,722: Patented March 27, 1923. Patentee: Walter R. G. Baker, Schenectady, N. Y.

MY present invention relates to high frequency signaling systems and more particularly to apparatus of the vacuum



Method enabling the duplex transmission of signals with extreme clarity at the receiving end.

tube type for producing and modulating high frequency oscillations for use in a signaling system.

One of the objects of my invention is to provide a system which will be capable of generating high frequency oscillations and supply them to a transmitting circuit. These may be in the form of speech modulated high frequency waves such as are used for radio telephony, interrupted continuous waves for radio telegraphy or continuous waves for radio telegraphy. Still another object of my invention is to provide a system in which vacuum tubes are employed for modulating high frequency waves.

The fact that radio has already taken a great place in religious work was again demonstrated when the City Temple, Lenox Ave. and 120th St., New York City, installed a powerful broadcasting set and station to allow many thousands of radio listeners to be within reach of church, even though they stayed home on Sunday mornings. The larger illustration at the top of this column shows the apparatus that has been installed to take care of the direct broadcast. R. Ketcham, who installed the set, is shown operating it on its final test before being put into actual operation. The wave meter, shown on the table, is a part of the equipment and readings are taken before every broadcast to assure the operators of WSAP that they are within the 360-meter wave. The apparatus is up to date in every manner, a standby listening-in system being used to enable the operator of the station to tell just how the music is going out and to correct any fault. The lower picture shows the way in which the microphone has been installed on the pulpit, shielded from the eyes of the congregation.

What constitute the rights of the air will be determined in a few days, when the first injunction suit ever instituted on the question will be tried at Levingston, Ill. E. McWilliams, a wealthy banker of Dwight, is suing Wylie Bergman, an amateur, claiming that his transmitter interfered with the former's receiving equipment to such an extent that it was impossible to listen in. Mr. Bergman's antenna and station are here shown. The money for mast and apparatus was obtained by doing odd jobs. The notables of the radio world are watching this case with intense interest.

Relative Capabilities of Double-Circuit and Single-Circuit Receivers

By E. E. Bucher

MISINFORMATION has been broadcast to the radio trade with regard to relative capabilities of the double-circuit and single-circuit receiver. By skilful distortion of certain fundamental technical facts, the public, as well as the jobber and dealer, have been informed and in some cases led to believe that the two-circuit tuner enables one to obtain unusual results which cannot possibly be secured with the single-circuit tuner.

There are, however, certain outstanding facts in the situation which no amount of propaganda can contravene:

First—The interference sometimes encountered in radio broadcasting reception is primarily a problem of broadcasting transmission. It can be fully eliminated only by the enactment of suitable government legislation that will enable wave lengths other than 360 and 400 meters to be assigned to broadcasting stations.

Second—No receiving tuner, whether it be of the single or double-circuit type, will prevent two broadcasting transmitting stations operating identically on the same wave length from setting up interference in the receiving set, unless the signals of one station are of sufficient intensity to drown out those of the other station.

Third—Two broadcasting stations operating on nearly the same wave lengths will produce an audible note or "whistle" in a receiving apparatus, which no tuner of either the single or double-circuit type will eliminate. The cure for this problem is the assignment of wave lengths to the transmitting stations of sufficient separation so as not to produce an audible note.

The single-circuit tuner will enable the listener to differentiate between two local broadcasting stations by one of two ways, (a) by connecting a .001 mfd. fixed condenser across the antenna and ground binding posts, or (b) by erecting a short antenna 15 to 40 feet in length and not of too great height. It has been conclusively demonstrated that a low antenna gives greater selectivity than a high antenna.

Selectivity in regenerative receiving sets is primarily dependent on the amount of regeneration. Two local broadcasting stations on different wave lengths will often interfere with one another on either the single or double-circuit receiver, but this is due to the overwhelming power of the transmitter which causes the apparatus to respond even when not accurately tuned to the transmitter. It has been demonstrated beyond all cavil that interference set up by two local stations can be eliminated on the single-circuit receiver by an antenna not exceeding 40 feet in length.

The ordinary regenerative set with the double-circuit tuner gives from 20 to 50 per cent less signal than the single-circuit with the same number of tubes and the same general circuit. In other words, stronger signals will be obtained, in long distance reception, from a single-circuit set than from a double-circuit set.

For those who have interest in long distance reception, as well as local reception, it is sometimes advisable to erect two single wire aerials, one for long distance reception—which may be of any length up to 150 feet, and the other for local reception—which may be of any length up to 40 feet, depending upon the sensitiveness of the receiving instrument. The small antenna enables one to differentiate between local signals, while the large antenna can be used for long distance work after the local stations have discontinued.

Many users of broadcasting sets are now installing two antennae—a long one for long distance reception after the local stations have closed down, and a small one, or an indoor aerial, for local reception. The indoor aerial may consist of 25 to 50 feet of lamp cord concealed behind the picture moulding, or a piece of inconspicuous No. 28 wire stretched across the corners of the room. Listeners located up to 15 or 20 miles from a broadcasting station can often obtain all the signal audibility necessary for local work by concealing the antenna under the carpet of the living room or the library of the home.

The foregoing are technical points which will stand the closest analysis. Speaking purely from the practical phases of the matter, the single-circuit tuner is, without qualification, the most suitable for the novice, that is, for the user unskilled in the art; for generally, the multiplicity of knobs involved in the operation of the double-circuit tuner places them beyond the stage of practicability for the non-technical public. Single-circuit tuners were designed primarily with the idea of providing simplified operation, and as such, they enable the novice to obtain results which can only be secured from the double-circuit tuner when the user possesses an intimate knowledge of the technicalities of the art.

Comparing collectively the advantages of the two types of tuners, it is clear that the single-circuit tuner is by far the more useful to the average member of the family, as it enables picking up far distant or local broadcasting stations with a minimum number of adjustments. Usually the distant station can be found on the single-circuit tuner several minutes before it can be located on a double-circuit tuner, to say nothing of the increased strength of signal which the single-circuit set provides.

For long distance reception, it is preferable in every case to install an outdoor antenna in a free open space keeping the lead-in away from the building and bringing it as directly to the receiving apparatus as possible. The antenna is preferably kept at the maximum distance from the trolley car lines, power lines, trees, buildings, etc., whereupon a marked increase in selectivity and in signal strength will be obtained. Lead-in wires should not be tacked to wooden mouldings or laid parallel to metal mouldings.

Heard Over the Radio Counter

EPISODE XV.

"'Lo, Bill! How are you?"

"Well, holy oscillators and jumping regeneration, Jack, where did you fall from?"

"Oh, just got back from the zone. Guess I'm here permanently now. What's new?"

"Oh, say, you don't know anything. Everything is changed since you went away. Why, even crystal detectors are coming back. What do you think of that?"

"Ahah, quit your kiddin'. I read the papers. Some bunch got across during the tests, didn't they?"

"You said it. Say, what are you goin' to do—set up another station, or stay away from it altogether?"

"Stay away! I should say not. I'm going to rig up a set that's going to be the crocodile's cough. Say, what kind of a tube is that over there? No, not that one; the one next to it."

"Oh, that's a new tube the G———— Electric just brought out. It's a pip, kid; you can't beat the tubes they are turning out now-a-days."

"Go on. I'll bet a stack of wheats in Childs' against a diamond tiara that they aren't as good as the old tubular audions that they used to turn out."

"O. K., OM; you're on. Come over here and listen to this tube work in any set in the house. Take your pick."

"Well, let's try it on that two-step regenerative over there."

"Well, there is Atlanta, Georgia. Is that plain enough?"

"Sure! Let me work that set for myself. It's been so long since I worked a regular set that I don't know how to turn the dials any more. Say—SSSHHH! It's a 6—O, boy! Gimme two of these tubes quick before I change my mind and buy a dozen."

"O. K., OM. Come on up to the house tonight and listen to some real DX on a three-step radio frequency with just a loop. I get them all."

"Sure! Say, rustle up that change, will you? I want to get home. I think the bug bit me all over again."

Coming! New List of Broadcasters!

While the Department of Commerce has assigned wave lengths for each of the broadcasting zones established by the recent Second National Radio Conference, individual assignments of station wave lengths have not been announced. They are being arranged as rapidly as possible and as soon as finished A COMPLETE, UP-TO-DATE LIST OF BROADCASTERS will be published by RADIO WORLD.

The allocation of wave lengths for Class B stations appears elsewhere in this issue of RADIO WORLD.

"Killing Two Birds With One Stone"

TWO merchandise radio goods successfully the manufacturer needs, first, to sell the trade and then the consumer—two birds that need a killing.

The trade hesitates about stocking goods until there is a consumer demand, and the consumer cannot buy until the dealer is stocked, for the average man is not a mail-order buyer; so this is the stone radio manufacturers stumble over.

RADIO WORLD is a "fan" weekly. Seventy odd thousand read it weekly to learn what kind of a radio receiving set to buy or how to improve, add to, or make work better the radio equipment they now have.

Each Thursday RADIO WORLD goes to press with every bit of radio news and information that breaks up to midnight, and, wherever you live, your nearest newsstand has RADIO WORLD the following Wednesday morning, while the monthly radio publications trail along with the news six to eight weeks after.

A radio dealer or jobber must be as well informed as his buyers (the consumers). When asked about the Armstrong, Flewelling, Reinartz, or Hazeltine circuits Mr. Dealer cannot very well say to Mr. Consumer: "In six or eight weeks I'll get the information from some radio monthly and then I'll be able to wait on you intelligently."

No, Mr. Dealer does not say this. He sends in his six-dollar subscription. *He reads* RADIO WORLD *each week as a matter of business necessity.* Unquestionably more radio dealers and jobbers read RADIO WORLD than any radio trade monthly.

Here, then, is how two birds can be killed with one stone—i. e., by advertising in RADIO WORLD 70,000 live radio buyers (consumers) are reached, and, simultaneously, almost one hundred per cent of all the radio dealers and jobbers read your advertisement.

RADIO WORLD is the weekly radio publication that creates demand, reaches the buyers, and sells both the consumer and the dealer with the one advertisement.

Circulation is less important in RADIO than READER INTEREST. For instance, the same keyed advertisement was run in RADIO WORLD and in another publication of over a million guaranteed circulation. RADIO WORLD brought cash returns of over two to one. Why? The million copy publication was bought because it contained good literature—RADIO WORLD because it supplies the radio information desired. This is one reason why thousands choose to pay three times as much per copy for RADIO WORLD as for the *Saturday Evening Post.*

Now the Theatrical Managers Want Broadcasting Royalties

THE Producing Managers' Association of New York City does not intend that royalties for broadcasting shall flow only to the American Society of Composers, Authors and Publishers.

On behalf of the producing managers, Arthur Hammerstein issued last week an announcement that no music from any opera, musical comedy or musical play would be permitted without the consent of the producing managers.

The musical plays now being produced, as well as other plays, are the property of the producers, Hammerstein contends. Any play, once delivered over to its producer, cannot again be bartered by the author or composer, or by any organization of authors and composers.

Broadcasters, the royalty line forms on this side!

"Synthetic Resins and Their Plastics," by Ellis

SYNTHETIC RESINS AND THEIR PLASTICS," by Carleton Ellis, consulting chemist, has been received from the Chemical Catalog Company, Inc., of New York. It is a highly technical, historical and comprehensive dissertation on the chemistry, compounding and uses of synthetic products of a resinous character. Some of these, such as bakelite, are used in radio work for insulating purposes. The price of the book is $6.

Radio Market Possibilities Abroad

MR. JULIUS KLEIN, director of the Bureau of Foreign and Domestic Commerce of the Department of Commerce, recently stated that conditions affecting the market possibilities for radiotelephone apparatus are changing rapidly throughout the world. Interest appears to be universal, and no branch of the electrical industry in recent years has been given such popular publicity as has radiotelephony. Broadcasting service is gradually being introduced in all the important countries, with a resultant brisk demand for receiving sets. Even people in isolated and remote regions, cut off from quick contact with the rest of the world, and fascinated by the possibilities opened up by radiotelephony, are installing expensive tube sets to enable them to hear distant broadcasting stations.

WEAF Capitulates on Broadcasting Royalties

THE dispute between the American Society of Composers, Authors and Publishers and broadcasting stations in and near New York over the question of copyright took a new turn last week, when Station WEAF, controlled by the American Telephone & Telegraph Company, and operated by the Western Electric Company, took out a license from the society. A contract was signed calling for an annual payment, which gives WEAF the right to broadcast any compositions the copyright of which is vested in the society.

No Wireless Receiving Set is complete without

The MAGNAVOX Radio

"The Reproducer Supreme"

MAGNAVOX products are designed in our own laboratories and manufactured in our own factory—greatly extended in size during the past few months.

The Magnavox Power Amplifier has been designed for use especially in connection with the Magnavox Radio, and its use greatly increases your range and signal strength.

Every owner of a Magnavox Radio should also add the Power Amplifier Model C if he has not already done so.

R-2
Magnavox Radio
with 18-inch Horn

FOR those who wish the utmost in amplifying power; for large audiences, dance halls, etc. Requires only .6 of an ampere for the field.

Price, $60.00

Type R-3
Magnavox Radio
with 14-inch Horn

THE same in principle and construction throughout as Type R-2, and is ideal for use in homes, offices, amateur stations, etc.

Price, $35.00

Magnavox
Power Amplifier
Model C

INSURES getting the largest possible power input for the Magnavox Radio. Can be used with any "B" battery voltage which the power tube may require for best amplification.

AC-2-C, 2-Stage $55.00
AC-3-C, 3-Stage $75.00

Magnavox Products may be had of good dealers everywhere.

The Magnavox Company
Oakland, California
New York Office: **370 Seventh Ave.**

Some DX Records to Shoot At

Tennessee, the Land of Songs

From Frank D. Sutton, Sparta, Tenn.

AM sending my "record" for publication in your DX Nite Owl Dept. It is a one tube set using the diagram published on the cover of Radio World, dated September 16, 1922. It is one using a variable condenser.

The following are stations, twenty in number, received in two hours and thirty minutes, which came in as loud as my two step regenerative: WGM, WSB, WBT, WBAP, WHAS, KDKA, WWJ, WMC, WDAJ, WOAN, WCX, WFAA, WJAS, WJAR, WCAZ, WDAF, WLK, WJAX, WHB, WSW. The nearest is 75 miles and the furthest, 750 miles.

Just Like the Lizzie, It Gets There Just the Same

From W. A. Cale, 296 Madison St., Brooklyn, N. Y.

This is a list of stations I have heard on one tube while DXing for less then a half hour on four different evenings. Several of them I heard on each of four evenings. Chicago and Kansas City come in particularly well, and are as clear as nearby stations.

WBS, WJZ, WOR, WAAM, WEAF, WHN, WOC, WDAP, WGM, WDAF, 2BR, KSD, WOS, WLAG, WMC, WIP, KDKA, WGY, WNAC, WGI, WLAK, WBAN, WBS, WHAS, WHAZ, 2XB.

The set costs about six dollars plus batteries, tube and phones. These latter items vary greatly with the type used. The set cost $14.45 complete. I shall be glad to answer any inquiries made by your readers.

Only Slightly Damp Around the Ankles

From A Constant Reader, 2316 Each Michigan Ave., Lansing, Mich.

JUST want to say that Mr. Keating's record for DX is the best ever, though I have copied some long-distance stations myself with humble galena, though not equalling his record by any means. My outfit consisted of 2-slide tuner, fixed condenser, ten-cent store detector and phones. Antenna 230 ft. long, 40 ft. high at farther end with 20 ft. lead in at lower end. With this outfit I have copied KDKA, WJZ, WOR, WHAZ, WOC, WCAE, WCX, WWJ, WDAP, WGY, WHB, and any number of code stations.

A "Nite Hawk" to the "Nite Owls"

From "Nite Hawk" Wm. L. Klein, Box 950, Newark, Ohio

I HAVE been a constant reader of your valuable magazine for about six months now and can truthfully say there is none better. Always up to the minute with new dope and circuits. Below you will find a "Nite Owl" record which I think will compare favorably with any I have seen so far. I have listened to stations in 25 states, Canada and Cuba. Following are some of the stations: CFCA, CFCN, KFI, KHJ, KFFQ, KSD, KYW, PWX, WBAP, WBAV, WBZ, WEAF, WGI, WGM, WGY, WHA, WHAS, WJZ, WLAG, WLAK, WLK, WMC, WOC, WPAC, WSB, WSY, WOAW, and many others I didn't enumerate. I am using a standard three-circuit set with two stages of audio-frequency amplification composed of the following parts: One general radio .001 primary condenser, one Kellogg variocoupler, secondary condenser, and variometer, Rhamstine and all American transformers, rheostats. I am using a detector tube called the "Vacobob" and WD-11's for my amplifier. This is a home-made set and I would like to see anybody better this record.

THE editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

High and Handsome from St. Louis

From Lawrence Levy, 5915 Lindell Blvd., St. Louis, Mo.

HERE is my record, using two sets. My aerial is two wires 80 feet long and 40 feet high. The ground is a wire attached to a pipe driven into the ground. One set is a single circuit tuner with two stages of audio-frequency amplification. The other, which I have just finished, is a one-tube set using the Flewelling super circuit. This has worked fine on either aerial or ground, as both cannot be used at the one time. I have received Schenectady, N. Y., on ground alone. I recommend this set to any one wanting a cheap long distance receiving set.

List of stations received: CFCA, CFCN, CJCG, KDKA, KFI, KFAF, KHJ, KOP, KWH, PWX, WBL, WBT, WCX, WGF, WGM, WGR, WGY, WHA, WHB, WJZ, WLK, WLW, WMC, WOC, WOH, WOI, WOQ, WOR, WOS, WPA, WSB, WSY, WWJ, WAAC, WAAL, WAAP, WAAZ, WBAP, WBAV, WCAE, WCAL, WCAW, WDAF, WDAJ, WDAP, WDAO, WDAV, WFAA, WGAS, WHAS, WIAA, WIAO, WJAN, WJAP, WJAX, WLAG, WLAL, WMAQ, WNAD, WNAV, WOAI, WOAN, WOAW.

A Thousand Miles on a One Foot Square Loop!

From George Bailey, Weston, Mass.

I WISH to thank you for the article on Reflex Hook-Ups by W. E. Thompson, in your March 3 issue. I have obtained really wonderful results, and wonder if readers realize what can be done with the hook-ups. I picked out the three tube set with the crystal detector, and put it together, following directions very carefully. For the plate resistances I used a variable grid leak, values 1,000 to 100,000 ohms, on the middle tube, and on the other tube a carbon potentiometer, values 0 to 5,000. Both of these instruments I had on hand, and found that they worked well. For tubes I used three U. V. 201, with 90 volts on the plates for volume, but 45 will work.

I made a loop just twelve inches square, with nineteen turns of ordinary insulated bell wire, and I put this in the circuit.

And now here comes the fun. I turned on the juice, set the condenser for resonance, turned the vernier on it, caught a carrier wave, then a girl singing came in loud. Weston is twelve miles from Boston, and as it was late for the local stations I thought I had New York, but to my surprise it was WDAP, the DRAKE HOTEL, CHICAGO! I hung the phones on the hook, got out my tape measure, and backed off twenty-five feet from the phones, and the music was plainly audible.

A little later I picked up WOC, DAVENPORT, IOWA, very loud and clear. Then WSB, ATLANTA GEORGIA! ! !

The set is surprisingly selective, as a swing of the loop cuts out WNAC completely, only twelve miles away, and a slight turn of the vernier brings in a distant station.

The two local stations, WNAC and WGI come in very loud on a Victrola with a tone arm attachment, and the modulation is almost perfect, as the crystal detector is much better than a tube for a detector in the case of clearness, and only a little less in volume.

To obtain good results, the plate reistances must be always used in tuning. The potentiometer must be set very carefully also. The loop condenser needs a vernier, and with care very sharp tuning is obtained. The rheostat on the third tube can be used for final adjustment, but is not important.

I have only been a "radio bug" for a year, but I have tried many hook-ups, and this one is best of all. I enjoy your weekly very much, and hope you will "Live long and prosper."

All on One Tube—Whee!!

From Henry A. Westermeyer, Cleveland, Wis.

RECEIVED my first copy of RADIO WORLD last week, and it sure is a fine radio magazine.

Herewith I send you a list of 34 broadcasting stations which I received February 15, 1923, from 6 p. m. to 12 p. m. on a single-tube set, no amplification, WKAQ, of San Juan, Porto Rico, and KFI and KHJ, of Los Angeles, Cal., being the most distant stations heard.

The mileage of the 34 stations is a total of 22,085 miles, which I think is very good for a one-tube set. My set is a "Michigan Junior," made at Grand Rapids, Mich.; and my antenna is 125 feet long, 35 feet high.

Call Letters	Location	Distance

WBZ Broadcasts Concert in French

GREAT interest was aroused in and around Springfield, Mass., last week, when a group of ten famous French artists visited the city to give a concert from radio station WBZ of the Westinghouse Electric & Manufacturing Company. These artists were sent by "La Presse," of Montreal, Canada, and their appearance was one of the big events in the musical season at Springfield.

This concert would seem to indicate a new era in radio broadcasting—this is, a traveling company from one station to another. It is possible that the exchange of artists by the large radio stations may be one of the future developments in this great art. Naturally any city, outside New York and Chicago, will utilize all available talent in a year or two and the same artists must perform over and over again. By the exchange of talent each city can gain a variety.

The artists were in charge of J. N. Cartier, the famous announcer from station CKAC of the Montreal "La Presse." He made the announcements both in French and in English. Mr. Cartier speaks both languages fluently and his speaking first in one language and then in another was a novelty in broadcasting.

WBZ was fortunate in securing Mr. Cartier to make the trip to Springfield, as he is considered one of the best of radio announcers. Besides being an excellent announcer, Mr. Cartier has had much experience as a newspaper man, soldier and wireless operator. He is a direct descendent of Jacques Cartrier, one of the earliest pioneers of Canada, and possesses the roving spirit of this forbear. He was a wireless operator before he was twenty years old and has had many experiences in the frozen North.

Radio Controlled Airplane

A THREE HUNDRED horse-power Voisin bombing airplane, carrying two passengers, made a flight last week, all movements of which were controlled by radio from the ground. The demonstration was made at the flying field at Etampes, France, and was directed by Captain Boucher, of the French air service, from a hangar, in which was located the switchboard for controlling the airplane's movements. The landing was made without difficulty.

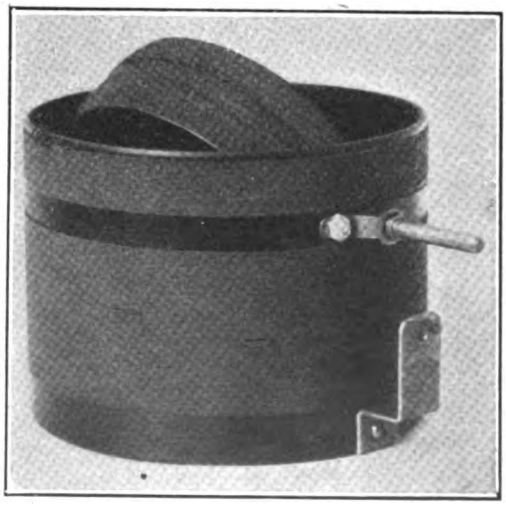
TO GET THAT DISTANT STATION
USE A COAST COUPLER

This coupler is designed along strictly scientific lines, and is the result of eighteen months' experiment. Wound with green silk covered wire on Bakelite tubing. Very selective.

Following are a few of the many DX stations received with this coupler, and detector tube only, at Long Beach, California:

PWX, Havana, Cuba
WWJ, Detroit, Mich.
WSB, Atlanta, Ga.
WDAP, Chicago, Ill.
CFCN, Calgary, Can.
WBAP, Ft. Worth, Texas



Our adaptation of a popular hook-up furnished with coupler. Coupler fully guaranteed when hooked up according to instructions.

Coupler and diagram, sold only under our money back guarantee. Mailed anywhere in the United States upon receipt of $5.00. Post Office or Express money order.

Combined Condenser-Grid Leak

A NEW product of the Charles Freshman Company, New York City, and one which will prove a very popular addition to their ever-increasing family, is a combined condenser and grid leak made for panel mounting. With this new product it is not necessary to muss around the inside of a set, when it is necessary to change the capacity of the leak, but by having it handy on the outside, the change can be quickly made. In construction it much resembles the old and well known product but, being square, looks very well on any panel. Two machine screws with nuts and washers project through to the back making it necessary to drill only two small holes

New Radio and Electric Firms

Advantages of the Hazeltine Neutrodyne Circuit

PROFESSOR L. A. HAZELTINE in commenting recently upon his new receiver, now widely known as the "Hazeltine neutrodyne receiver," said in part: "The neutrodyne circuit is in effect a desirable simplification of all previous circuits and not, as many people think, an elaboration. In eliminating certain disturbing features that now exist in present sets, I, of course, had to change the design of several of the parts that are thought to be standard; but in doing so, I eliminated all previously existing disturbing features so that perfect relay amplification was possible. This circuit will get the utmost out of a received signal that can be had, without any extraneous noises, and with the least possible amount of tuning controls."

Where Push and Pull Transformers May Be Obtained

The article on a power amplifier by C. White, published in RADIO WORLD for February 24, 1923, apparently has created great interest among amateur builders. Numerous letters have been received by the author and RADIO WORLD inquiring where the push and pull transformers mentioned in the article can be obtained. In reply to these inquiries RADIO WORLD is requested by Mr. White to state that they may be secured from the General Radio Company, Cambridge, Mass. Letters addressed to Mr. A. F. Murray, in care of the Engineering Department of this company, will receive his personal attention and prompt action.

Injunction on Radio Tubes Vacated

THE Circuit Court of Appeals has vacated an injunction obtained by the Radio Corporation of America which restrained Jacob Hohenstein, Louis M. Rosenthal and the Liberty Appliance Corporation, of New York City, from continuing an alleged infringement of the De Forest radio vacuum tube patents. The opinion of the court was to the effect that the plaintiff was without right to sue and that it had no title to the patents.

Sunbeam Has New Outlet for Its Goods

The Sunbeam Electric Company, 71 Third Avenue, New York City, has added a new outlet for its radio and electric products by the purchase of the business which has been conducted successfully for ten years by John Ryffel at 207 East Fourteenth Street, New York City. Complete radio equipment of Sunbeam standard will be available at either address.

A New One Tube Set

The Aldwin Radio Company, 676 Eighth Avenue, New York City, have brought out a new one tube set, using an original circuit of their own. The features claimed for the set are its remarkable sensitivity combined with simplicity of operation. The tuning is accomplished with a single dial. Stations can be tuned in or out with two

Partial Program of WGI, Medford Hillside, Mass. 360 Meters

Saturday, April 28, 1923.

6:00 P. M.—New England Weather Forecast, furnished by the U. S. Weather Bureau. Late News Flashes, Early Sports News—Boston American.

6:15 P. M.—Condition of Massachusetts Highways, furnished by the Automobile Legal Association. Amrad Bulletin Board.

6:45 P. M.—Code Practice, Lesson Number Forty-two.

8:00 P. M.—Evening Program.

1. Fourth of a series of talks on New England problems under direction of the New England Business.
2. Musical Program to be announced.

Sunday, April 29, 1923.

4:00 P. M.—Twilight Concert.

1. Concert by the Mal-Con Band of Malden; Mr. C. Roland Reasoner, Director.
2. "Adventure Hour," conducted by the Youth's Companion.

8:30 P. M.—Federation Church Service, conducted by Rev. Lyman J. Radcliffe.

Program of WGY for Week of April 29

ALL time references in the program of WGY, the Schenectady broadcasting station of the General Electric Company, are on the basis of Eastern Standard Time. Several changes have been made in the schedule to accommodate the program to all communities, whether under "old" or "new" time. The concert programs remains at 7:45 p. m., Eastern Standard Time, or 8:45 p. m. Daylight Saving Time.

Sunday morning and evening WGY will broadcast the services of the Albany Street Methodist Church and in the afternoon the WYG Symphony Orchestra will give a program assisted by soloists.

Thursday night, Winchel Smith's comedy, "The Fortune Hunter," will be produced by the WGY Players. During the first program, Friday night, May 4, "Daniel," nationally known sport writer of the New York "Herald," will talk on the prospects of the 1923 baseball season. A second address will be delivered by W. C. White of the Research Laboratory of the General Electric Company. Mr. White will talk on "The Radiotron."

At the late concert, Friday night, May 4, the Union College Musical Clubs will have the entire program. Saturday evening Cain's Castle Orchestra will play from 8 to 10, Eastern Standard Time.

Exchange Bars Stock Boosting by Radio

THE Governing Committee of the New York Stock Exchange, at its last semi-monthly meeting, adopted the following resolution:

"RESOLVED, That no member of the Stock Exchange, or firm registered thereon, shall make use of wireless or radio to transmit or broadcast market information or forecasts of business or financial conditions or any other matter intended to advertise such member or firm or to stimulate interest in particular securities or in the market; provided, however, that members may supply quotations to broadcasting stations which have been approved by the committee at such intervals and under such regulations as are prescribed by said committee."

A SENSATION

In New York and now Gaining an Enthusiastic National Reputation

KAUFMAN CIRCUIT

Designed by an Amateur and Dedicated to Radio Fans for Better Reception.

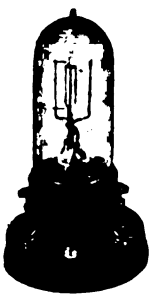
This Circuit acts like a three-star general, dependable, broad gauged and definite. It makes a recreation out of a fad. The wonderful results achieved on this marvelous circuit have forced us to turn over a New Department to handle the Kaufman Circuit exclusively for our Mail Order Patrons. You can get the whole circuit complete with a simple and clear diagram as follows:

KAUFMAN CIRCUIT, Drilled Panel, Active 20 Variocoupler, 46 Plate Vernier Condenser, Vern. Rheostat, Socket, 2 Variable Grid Leaks, .00025 Micon, .001 Micon, 34 Switch Points, 3 Levers, 2 Dials, 8 Binding Posts—ALL at This Specially Low Price. **$12.50**

Write out your order and pin a Post Office Money Order to it and Mail it to us. If you ask for our Catalogue, Given Free, you will learn of the Radio Instruments we offer for DX (Distance) work. Checks or stamps not accepted. Merchandise shipped postpaid East of the Mississippi.

D-X-Radio Co.

123 Liberty St. New York City



Na-ald W.D. 11 No. 411

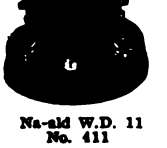
It's the contact that counts

The dual-wipe contact strips of the Na-ald DeLuxe socket avoid the trouble experienced with the socket of conventional design. Because of thorough cure and high dielectric properties this socket keeps plate to grid losses at a minimum (of particular importance in Flewelling Circuit or in Radio Frequency).

Price 75c

The Na-ald Special Socket No. 499 is a sturdy little socket for the G. E. No. 199 dry-cell tube. It has special slot construction, and is molded of genuine Bakelite. The heat from soldering connections will not affect these sockets.

Price 75c
After May 20, 50c



Booklet with wiring design and instructions for Hazeltine's Neutrodyne circuit, together with other selected circuits, packed with each Na-ald product or sent in exchange for cover taken from any Na-ald carton.

Answers to Readers of Radio World

Has RADIO WORLD *ever published a picture of Radio Photography? Who is responsible for the present invention?—James Mason, Three Rivers, Mich.*

RADIO WORLD first published a picture of this kind in its June 24, 1922, issue. It was of a photograph that was sent from Rome, Italy, to Bar Harbor, Me., in forty minutes, utilizing the invention of Dr. Korn, of Berlin. The present device is the invention of C. Francis Jenkins, of Washington, D. C.

* * *

Kindly publish a diagram of a one-tube reflex similar to that used by Lionel Bigman, illustrated in RADIO WORLD *for April 14.—C. T. Brown, 770 Flatbush Avenue, Brooklyn, N. Y.*

Herewith is a similar hook-up. It is a one-tube reflex that will permit you to use either a loop or an antenna by simply hooking either across the terminals marked A and B. The constants are marked so that

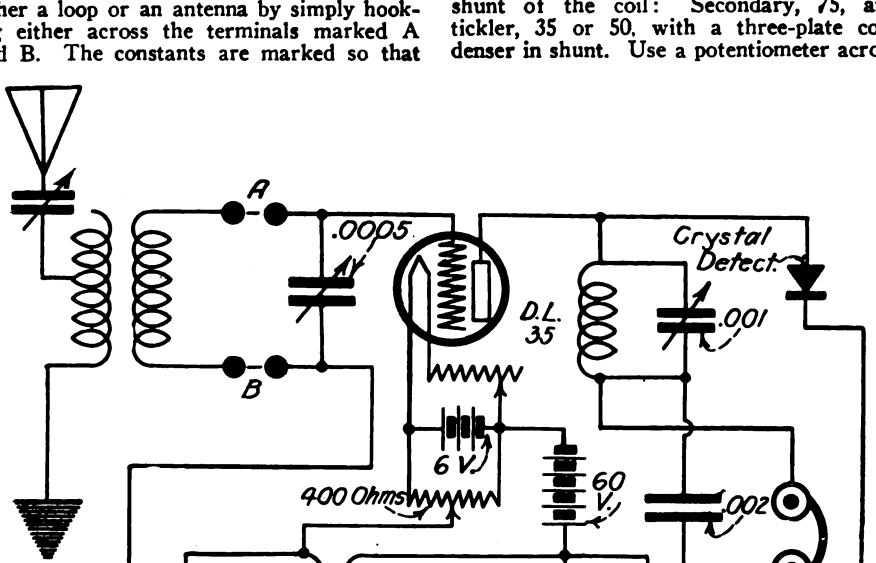

Diagram of a single tube reflex set using a crystal detector, asked for by Mr. C. T. Brown. Either tuner with antenna and ground or loop can be used simply by inserting the desired leads at A and B. If loop is used, the tuning is done with the condenser in shunt of it. The circuit shown is very selective and extremely sensitive, if a good tube is used.

no mistake can be made. The condensers .002 are fixed, and can be obtained at any radio shop. The variable condenser used in the plate circuit across the honeycomb coil should be one that has little dielectric loss, and the rotor side of the plates should go to the side connected to the audio-frequency transformer.

* * *

Inasmuch as the reflex circuit accomplishes the greatest detection and amplification for a given expense of tubes, why is it not more universally adopted? What are the objections to this circuit, if any? Where two stages of radio-frequency are used, is it necessary to alter the design of the transformer in the second stage?—D. S. McLane, 329 Harrison Avenue, Schenectady, N. Y.

The reflex circuit is very popular. Compared to other multi-tube circuits the reflex circuit is more widely adopted than any other. Because of the fact that it can be used with a loop antenna and saves tubes as well as current, by using one tube instead of two, it is the most economical circuit embodying radio- and audio-frequency. There are no objections to this circuit outside of the fact that the wiring is slightly more complex than most circuits, which is really not an objection at all. The same type transformers can be used in the first and second stages if tuned radio frequency is not used.

* * *

Using the enclosed hook-up with two stages of audio-frequency I am able to receive 360 and 400 meters, but when I attempt to receive KFI and KHJ on 430 the set seems to "freeze," and I can only hear them faintly through the interference of the other stations. What is my trouble?—Gene Ullemeyer, 1511 9th Avenue, Rock Island, Ill.

We note that you are using honeycomb coils. Try using the following for the primary 100, with the primary condenser in shunt of the coil: Secondary, 75, and tickler, 35 or 50, with a three-plate condenser in shunt. Use a potentiometer across the filament and battery leads to get rid of the bluing of the tube. Don't use so much filament current.

* * *

I am using a radiotron tube, on four dry cells hooked in series. Is this as satisfactory as a six-volt storage battery?—C. A. Waldron, 1330 West Broadway, Minneapolis, Minn.

From an operating standpoint it is as good, but from an economic standpoint it is not so good. A set of dry cells will last about 60 active working hours, using one tube, which is not much considering the amount a tube is really used. You can therefore readily see that the money spent in constantly renewing dry cells will be more in the end than the price of the storage battery.

* * *

Kindly give me hook-up employing variable condenser, variocoupler, two transformers, and necessary tubes and sockets.—Fred Bingold, Hudson Motor Car Co., 315 West 68th Street, New York City.

We refer you to the article by Arthur S. Gordon published in RADIO WORLD for April 14, where you will find the hook-up you desire.

I have constructed the receiver described by Geo. May, in RADIO WORLD *for July 1. It is the circuit using two variometers and a variocoupler. In the article it advises to tune the grid variometer between two squeals. I cannot even get the set to squeal, and signals don't come in any louder than on my crystal set. What can my trouble be?—Wm. C. Martin, Hand Station, Michigan.*

This circuit is the "old reliable" three-circuit Armstrong regenerative circuit, and you should get the squeals you mention. Try the following: Increase your B battery current and also put your grid variometer on the other side of the secondary (rotor) of your set, next to the grid condenser and grid leak. Use a variable grid leak resistance in the circuit.

* * *

I have constructed the set described in RADIO WORLD *for January 20 by Orthcrus Gordon and have not had much success with it, outside of burning out two tubes. I have seen two or three good reports on this circuit, and yet cannot seem to get it to work. I notice that the negative B battery goes to the plate. Is this right? Would this cause my tubes to burn out?—James Carroll, 24 King Street West, Toronto, Ont., Canada.*

The plus in this diagram should go to the plate. The fact that they are reversed would not tend to blow your tubes, but simply to render the circuit inoperative. The plus terminal of the plate should always go to the plate in any circuit. You must have your circuit incorrectly wired, in order to blow tubes with it. Trace your wires, and make sure that everything is correct.

* * *

What is necessary to obtain a license for the operation of a small transmitter?—Louis Gallinan, Box 83, Bridgton, Me.

In order to obtain a license for the operation of a transmitter it is necessary to do the following: Be able to transmit and receive signals at a fair rate of speed (ten words per minute; five letters constitute a word; so that is fifty characters per minute). Have a knowledge of the "Q" signals and their meaning and use. Know the international wireless regulations pertaining to the secrecy of messages and the operation of a station during a SOS call. Be able to understand and describe the receiver and transmitter that you are using.

* * *

I have built the set described by Orthcrus Gordon, but use a De Forest and U. V. 200 tube instead of the WD-11 mentioned. I get the music and talk but it is distorted. What is my trouble, and how can I remedy it?—A. R. Moulton, 114 Putnam Street, Watertown, Mass.

The fact that you are using different tubes should not make any difference in the operation of the circuit. Don't burn your tubes so high, and also sacrifice some of the volume for quality. A signal will sometimes be much cleared and distortion not so noticeable, if it is detuned a bit.

* * *

Can a WD-11 tube be used instead of a U. V. 201 in a circuit and what plate voltage will be required for it?—H. W. Zimmerman, 723 W. Washington Street, Jackson, Mich.

This particular tube can be used as either detector or amplifier and when used as amplifier should have either 45 or 67½ volts on the plates. These tubes will stand up to 150 volts on the plates, as stated in a recent article in RADIO WORLD.

General Electric Will Erect Two New Giant Broadcasting Stations

PLANS are nearing completion for the erection of two more giant radio-broadcasting stations by the General Electric Company, according to an announcement recently made by Martin P. Rice, director of broadcasting for that company.

One of the new stations will be located near San Francisco and the other is indefinitely placed somewhere between the Pacific and Atlantic Coasts. Both will be modeled after General Electric Company station WGY, at Schenectady, N. Y., and the experience gained by the engineers in this station after fourteen months' operation will aid greatly in the plans to give radio listeners in other parts of the country a radio service of the highest transmission quality.

Mr. Rice recently returned from the coast after a tour of inspection. He was accompanied by Harry Sadenwater, engineer in charge of the technical operation of General Electric Company's radio-broadcasting stations. Sites were investigated in and near Oakland and San Francisco, Cal.; Denver, Col., and Dallas, Texas.

In each city visited Mr. Rice received assurance of co-operation from the local chamber of commerce and municipal officials, who were alive to the advantages and prestige which may accrue to the city which is the home of a powerful broadcasting station.

The expansion of radio broadcasting by the General Electric Company from one to three stations is part of a program agreed upon some time ago by the General Electric Company, the Radio Corporation of America and the Westinghouse Electric & Manufacturing Company. This plan contemplates the erection of nine large broadcasting stations. Of this number the Westinghouse now has three in operation—those at East Pittsburgh, Pa.; Chicago, Ill., and Springfield, Mass. The Radio Corporation has two stations under construction—one in New York and the other in Washington, D. C. The New York station—illustrated in RADIO WORLD for April 14, 1923—is on top of the Aeolian Building, on Forty-second Street, and will be opened in a short time. The General Electric Company now operates WGY at Schenectady, N. Y.

In discussing the plans of the General Electric Company, Mr. Rice said: "It is our conviction that the future of radio broadcasting will be on a plane of relationship with localized stations, similar to that of the national magazine to the local newspaper. Each will have its own functions—the local stations to carry events of local interest and larger and more powerful stations to transmit events of national import and interest."

Singer Claims Increased Popularity Accrues from Broadcasting

AN artiste who takes exception to the recent agitation started by many performers against broadcasting their music by radio is Vivienne Segal, the charming young star of numerous New York productions. She takes issue also with many music publishers, writers of songs and manufacturers of phonograph records who have lodged a claim in Washington for royalties from the radio-broadcasting corporations, saying that their popularity and that of their songs is hurt by being heard over the radio. On the contrary, it is the contention of Miss Segal that it heightens one's

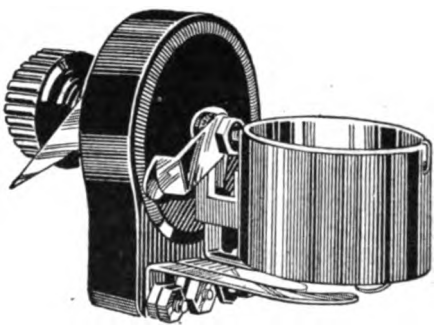
The Latest Book on Radio Telephony

William C. Ballard, Jr., Assistant Professor of Electrical Engineering at Cornell University, is the author of a very valuable addition to radio literature under the title, "Elements of Radio Telephony."

The reader with a technical background who desires to bring his knowledge of the subject down to date will find this exactly the book for the purpose. The radio enthusiast will find between its covers an excellent presentation of fundamental principles with their applications. The author is a recognized authority and the book is accurate, simple, clear, reliable and written in a pleasing style.

"Elements of Radio Telephony" retails for $1.50, and will be sent postage free on receipt of this price by the Columbia Print, 1493 Broadway, New York City.

AJAX SOCKET-RHEOSTAT



Combination Socket and Rheostat — Eliminates Wiring

A device for which amateurs and professionals have long been waiting.

A combination V. T. Socket and Rheostat for panel mounting which entirely eliminates separate leads between socket and rheostat and at the same time provides a panel-mounted socket without the use of additional brackets, thus materially simplifying the installation and hook-up.

Cat. No.	Type	Ohms	List Each
2007	A-1	5 with Knob and Pointer	$2.00
2008	A-2	5 ¼" Shaft without Dial	2.00

Unless otherwise specified, Type A-1 will be supplied.

From HLW to WOR and WOR to HLW

NOT long ago local radio fans at Williston, North Dakota, had the pleasure of picking up broadcasting station WOR, L. Bamberger & Co., Newark, N. J. On the evening the program from this station came in so clear the woman announcer of the station asked all listeners at a great distance from Newark to write that they had picked up the station. In response, H. L. Weatherwax, Williston radio fan, sent the following letter to WOR:

L. Bamberger & Co.,
Station WOR.

GENTLEMEN AND ANNOUNCER: Last evening I had to marvel at the (W) onders (O)f (R)adio because (W)e (O)verheard (R)eception of a (W)oman (O)f (R)efinement (W)ith (O)ur (R)eceiver. I (W)ish (O)ur (R)eply might contain (W)ords (O)f (R)espect for your (W)ish (O)f (R)eturn. However, (W)ith (O)ur (R)ambling of (W)himsical (O)ratorical (R)hetoric, I trust you will (W)rite (O)n (R)eceiving this kind (W)ish (O)f (R)egard.

Yours very truly,
H. L. WEATHERWAX.

In response the following was received last week from the broadcasting station at Newark, N. J.:

(H.) (L.) (W)eatherwax, N. D.

(H)onored (L)ong-distance (W)ireless Friend:

(H)ow (L)ong (W)e (H)ave (L)ingeringly (W)aited to say we (H)ave (L)iked (W)ords of (H)e who (L)istened (W)hen we broadcasted. (H)ow (L)ucky (W)OR (H)as (L)ately (W)andered to (H)omelike (L)ittle (W)illiston. (H)appiness, (L)ong Life and (W)ealth.

JESSIE E. KOEWING, "J.E.K.,"
Director, Chief Announcer and
(H)asty (L)etter (W)riter
of "WOR."

WOC Changes Its Wave Length to 400

STATION WOC, Davenport, Iowa,—"Where the West Begins"—has issued the following:

"Notice has just been received from the Department of Commerce that in accordance with recommendation of the Second National Radio Conference, recently held in Washington, each station is authorized to broadcast on only one wave length. This means that, beginning immediately, the Government Reports broadcast from WOC heretofore on 485 meters, will be sent out on the regular broadcasting wave of 400 meters."

American Telephone & Telegraph Co.'s Broadcast Schedule

MR. W. E. HARKNESS, Manager of Radio Broadcasting for the American Telephone & Telegraph Company, informs RADIO WORLD that it is the policy of his company to circulate its advance programs through the newspapers only.

The general schedule of broadcasting is as follows: On weekdays, 4:00 to 5:30 p. m.; evenings, 7:30 to 10:00 p. m., except Tuesday and Friday, when the schedule is 7:30 to 8:00 p. m. The Sunday schedule is 3:20 to 5:20 p. m. and 7:30 to 10:00 p. m.

Paris Catches Radio "Wild Cat"

"POSTE ZERO," which has so long disturbed the listeners-in in Paris has at last been discovered. The mysterious operator turns out to be a manufacturer of wireless apparatus who has been testing his installations over wave lengths equal to those of the Eiffel Tower. He has been warned to experiment on shorter wave

Helpful Hints to Hoosier Hams

DON'T fasten your antenna permanently to a bough of a tree if you want it to last. Fasten it by means of a pulley, with a heavy weight at the end, which will keep it taut, yet allow the tree to sway without breaking the wire.

The best possible ground is a wire dropped into a well, with a copper or zinc plate at the end of it. If you can't do this bury a dozen or so old tin cans and attach a wire to each one of them. This makes a good ground if the earth is moist.

Don't use an exceptionally long antenna just because you have the space to string it. Better results and sharper tuning will be obtained from an antenna 75 to 100 feet long than one of 200 feet, because the longer the antenna the broader the tuning on your set, and, consequently, the harder it is to tune in the long-distance fellows.

Keep your apparatus clean and free from dust if you want it to give you good service. A little bit of dust can form a high resistance leak across some part of your set, and you will wonder why it has suddenly lost its power to bring in the DX.

Don't use spring water in your storage battery. It may be the purest water in the state and yet contain enough mineral and metallic salts to ruin your battery. The cheapest way is to keep a supply of distilled water on hand. Boiled water is not distilled, so do not use it. It simply evaporates some of the water, killing the live organisms, and leaves the mineral and metallic salts in a stronger solution, if anything.

If you are troubled by clicking from party telephone lines run your antenna at right angles to the line, or, if that is not possible, put in a filter circuit, which will eliminate a great amount of it.

Don't run your antenna through trees. Trees will shield the antenna to a great extent, due to absorption, forming a sort of a protective screen around them, much the same as a tall building containing much steel will shield other buildings lower than it is.

If your set is located in the attic you can give your folks a chance to listen in by running wires downstairs and connecting a loud-speaker to them.

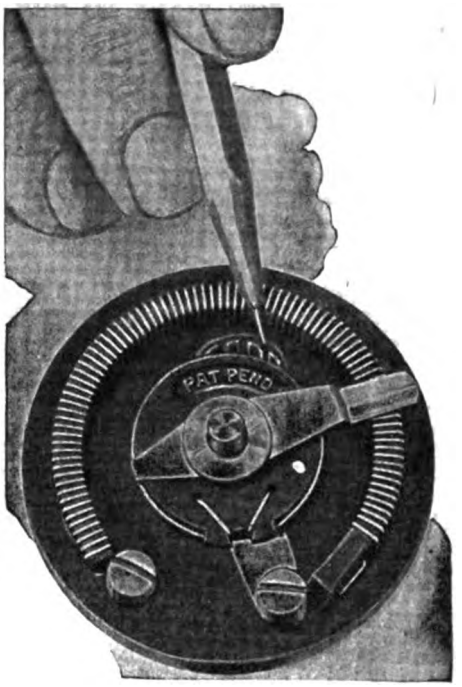
Every Electron a Miniature Radio, Says Sir J. J. Thomson

THE principles that underlie the electronic theory are essentially the same as make possible the sending and receiving of radio messages, it was stated by Sir Joseph John Thomson, the discoverer of the electron, before the Franklin Institute at Philadelphia last week in the fifth and last of his lectures on "The Place of the Electron in Chemistry."

According to Sir Joseph, who is Master of Trinity College, Cambridge, the electrons set up vibrations in the same way as do the sending apparatus of radio, and the wave lengths of the vibrations have been measured. The only thing the electrons lack is variable condensers, but these they hardly need.

The wave lengths between the electrons have been observed, and are known as photoelectric effects, according to Sir Joseph. The fact that mathematical calculations for their wave length practically check the recorded observation for several of the elements gives definite proof of the truth of the electronic theory, and vindicates the discovery of Sir Joseph.

Electrons are tiny negative charge points circling a positive nucleus in the atom. The degree of force exerted by the positive nucleus of the atom on the nearest electron determines the extent of the attraction or repulsion. The nucleus attracts the electron, but other negative electrons repel it, and



Fada Vernier Rheostats

used on your radio receiver brings in broadcasted concerts from stations thousands of miles away—by giving super-delicate control of the filament current of the detector tube.

Fada rheostats and potentiometers are practically standard with hundreds of thousands of radiophans who construct their own radio receivers.

120-A Rheostat (5 ohm)	$0.75
121-A Power Rheostat (1½ohm)	1.20
150-A Vernier Rheostat (5 ohm)	1.25
151-A Ver. Attachment	.50
152-A Potentiometer (200 ohm)	1.00
153-A Rheostat (8 ohm)	1.00
154-A Potentiometer (400 ohm)	1.00
155-A Vernier Rheostat (8 ohm)	1.50

Send 10c for a copy of the FADA Handbook—a real aid to your experimental work.

CRAM'S RADIO BROADCASTING MAP of the UNITED STATES & CANADA. Scale 100 miles to the inch. In two colors, size 34x28. Printed on high-grade map paper, up-to-the-minute information, indicating all amateur and standard broadcasting stations, with complete index to stations. 35c postpaid. The Columbia Print, 1493 Broadway, N. Y. C.

20c RADIO BOOK. Make your own and operate. (Illustrated.) Phipps, 1014 Belmont, Chicago.

FOR SALE—5-dial omnigraph, fine condition, only $7.00. 2 Murdock sockets, 60 cents each. Robert McConnell, Urbana, Ohio.

START YOUR OWN BUSINESS. Write to the Circulation Manager of RADIO WORLD and learn how you can get subscriptions for this publication. Start a business of your own which will bring you in money right along. Liberal terms to energetic young men. RADIO WORLD, 1493 Broadway, New York.

BUILDERS AND EXPERIMENTERS. Do you know that the Reflex circuit is one of the most interesting circuits to construct? You can not guess how much fun you are missing if you fail to try out at least one of these circuits. See RADIO WORLD issues of Feb. 24 and March 3. They contain two fine articles by W. S. Thompson, with plenty of new Reflex circuits to experiment with. Don't miss these! 15c. a copy. RADIO WORLD, 1493 Broadway, New York City.

IF YOU ARE A REGULAR RADIO fan and like to hear the stations in the four corners of the United States come in with a bang, then you will want the Flewelling Circuit. If you do, send 15c for RADIO WORLD, issue of Feb. 24, which contains complete description and directions for the manipulation of the circuit. RADIO WORLD, 1493 Broadway, New York.

RADIO FREQUENCY AMPLIFICATION. Get the best results with radiophone reception. Long distance reception, purity and volume of tone reproduction, static reduction and selectivity. We have working plans, blue prints, with exact specifications of parts to assemble to construct a three tube set. Gives marvelous results. Save worry and experimentation in building one of these sets. Any amateur can build. Guaranteed results. Sent for $1.00, postpaid. Research Laboratories, Carthage, Mo.

SUPER-SIMPLICITY CIRCUIT—1,000 to 1,500 miles on one tube, one control, 150 to 25,000 meters. No rheostat, storage battery, vario coupler, variometer, 3-coil mounting, variable inductance, taps or radio frequency. Nothing to guess about. Complete hook-up and particulars, $1.00. No checks. Build your own. Save 50% and get better results. RADIO EXPERIMENTAL LABORATORY, Box 194A, Berkeley, Cal.

RAND-McNALLY RADIO MAP OF UNITED STATES—Is 28 x 30 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover. Price, 35c. The Columbia Print, 1493 Broadway, New York City.

EXCHANGE LETTERS with friends everywhere. Pleasant pastime. Information for stamp. Smith, Box 3125, M. Portland, Ore.

TWENTIETH CENTURY BOOK OF RECIPES, FORMULAS AND PROCESSES—Edited by Gardner D. Hiscox. This book of 800 pages is the most complete book of recipes ever published, giving thousands of recipes for the manufacture of valuable articles for every-day use. Hints, helps practical ideas and secret processes are revealed within its pages. It covers every branch of the useful arts and tells thousands of ways of making money and is just the book everyone should have at his command. The pages are filled with matters of intense interest and immeasurable practical value to the photographer, the perfumer, the painter, the manufacturer of glues, pastes, cements and mucilages, the physician, the druggist, the electrician, the dentist, the engineer, the foundryman, the machinist, the potter, the tanner, the confectioner, the chiropodist, the manufacturer of chemic novelties and toilet preparations, the dyer, the electroplater, the enameler, the engraver, the glass worker, the gold-beater, the watchmaker, the jeweler, the ink manufacturer, the optician, the farmer, the dairyman, the paper maker, the metal worker, the soap maker and the technologist in general. A book to which you may turn with confidence that you will find what you are looking for. A mine of information up-to-date in every respect. Contains an immense number of formulas that everyone ought to have that are not found in any other work. New edition. 807 octavo pages. Cloth binding. Price, $4.00. The Columbia Print, 1493 Broadway New York City

RADIO BROADCASTING MAP

FOR the benefit of those interested in Radio and those who are becoming interested, Rand McNally & Company have prepared a publication containing a wealth of information of greatest value. It shows in the most comprehensive way the location of the broadcasting stations, gives their classification, the call letters, wave lengths, ownership, etc., of each.

Everyone who wishes to get the maximum pleasure and enjoyment from Radio should have a Rand McNally Radio Map of United States. It is complete, accurate and up-to-date.

The Rand McNally Radio Map of United States is 28x30 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

An Idea for the Experimentally Inclined

SOMETIMES, when a "ham" has made his set, and feels confident that it embodies the utmost of everything, he sees another circuit that captivates his fancy, and he is inclined to rip out the one he has just finished and build the new one.

This can all be eliminated in the following manner, when worked out neatly: Make up your panel, incorporating all the apparatus you can use, such as variometers, variocouplers, a couple of variable condensers, several values of fixed condensers, transformers and tubes. Then, instead of wiring them directly, bring each instrument out to small jacks, such as are sold in the stores and take up about an eighth of an inch of panel space. Now make up a series of small bridging cords with the plugs on either end. It will then be very easy for you to incorporate any number of hook-ups just by changing the connections. It is of course understood that all the apparatus is to be mounted on one panel, and that the panel will be large enough to accommodate everything. This is discounted by the fact that you can try out any number of queer circuits, just by shifting your cords.

Try it out, fellows! It works marvelously well and you can change your hook-up to suit your mood. If you feel like trying out an Armstrong, all you have to do is to switch your leads, insert your plugs, turn on the juice, and listen. Then if you decide that you would rather listen to the tune of a single circuit, it is a matter of five minutes to change your circuits through the agency

ADDRESS SERVICE EDITOR, RADIO WORLD, 1493 BROADWAY, NEW YORK CITY

Amplified Three Thousand Billion Times

IMAGINE a man big enough to haul at one time all the freight moved in the United States in a year! But an average man could perform that super-Herculean feat if his strength were amplified as much as is the tiny flow of power from a radio-telephone microphone before it reaches the transmitting antenna.

In the studio of WEAF, the American Telephone & Telegraph-Western Electric radiophone station in New York, is a microphone of the condenser type. The minute capacity change which occurs when voice waves impinge upon the exposed plate of the condenser microphone causes a change in potential on the grid of a three-element vacuum tube.

This tube and others amplify the feeble output of the microphone and overcome the resistance of the wire line from the studio to the Western Electric Company's building on West Street. Here other tubes increase the power to such magnitude that they control the output of WEAF's high nower oscillator tubes. From studio to antenna the power is amplified three thousand billion times.

To help you conceive this figure, imagine what an average man could do if his strength were amplified to that degree! Imagine all the locomotives of the United States working at their highest capacity, moving the largest haul in our history, as they did in 1918. That year our total freight movement was 408,011,453,783 ton miles. Not only could this amplified man move all that freight traffic and replace all the locomotives in our freight service, but he would find the task as easy as you find lifting a four-ounce weight. This imaginary giant could perform a similar service for 400 countries at the same time, each handling a tonnage of freight equal to that of the United States. Not only would this giant be endowed with immense power, but were he as sensitive as the amplified current to the variations in the microphone circuit he could control this immense power with the utmost flexibility, increasing and decreasing the speed of the giant freight system between minimum and maximum as frequently as 3,000 to 5,000 times per second.

Lord Robert Cecil Instructs a Class by Radio

LORD ROBERT CECIL probably doesn't know it, but he acted as professor for "History Six," the class in Modern European History at Haverford College, Philadelphia, for three-quarters of an hour on a recent day. Dr. Kelsey, who is the usual instructor for this class, was anxious that his pupils should have the advantage of learning, first hand, about the League of Nations, and arranged to have a powerful three-tube receiving set and loud-speaker installed in the classroom so that the entire speech delivered by Lord Robert Cecil at the Bellevue-Stratford, and broadcast by Station WFI, Strawbridge & Clothier, could be heard. At 1:30 p. m. the class of thirty-five undergraduates, armed with notebooks and pencils, assembled in the classroom and listened to the distinguished English statesman until 2:10 p. m.

Radio Church of America

THE church will be brought direct to the people by radio under a plan proposed by the Radio Church of America, which has been incorporated at Sacramento under the laws of the state of California, and purports to be non-sectarian and non-denominational. Headquarters of the church are to be established in San Francisco. Branches will be established, according to the articles of incorporation, wherever and whenever a radio broadcasting station is available.

Facts About Foreign Radio Stations

IN compliance with a number of requests the following information is supplied by the Department of Commerce for the benefit of all concerned: Nauen, Germany, call letters, POZ; range, 6,500 miles; w.l., 3,100, 4,900, 5,600, 6,300, 8,700, 9,800, 13,000. Kootwijk, Sambeek, Holland, call letters, PCG; range, 5,000-6,000 miles; w.l., 6,250, 8,400, 12,500, 16,800. Stavanger, Norway, call letters, LCM; w.l., 12,100. Bordeaux-Lafayette, France, call letters, LY; power, 500 KW arc. Lyons, France, call letters, YN; power, 60-200 KW. Eiffel Tower, France, call letters, FL; power, 40 KW. Basse Lande (Nantes), call letters, UA; power, 200 KW.

Alaskan Radio Stations Reopened

THE following radio stations in Alaska have been reopened: KKA, Yakutat; KOXN, Pirate Cove; KJK, King Cove; KXW, Ikatan.

ELEMENTS OF RADIO TELEPHONY

By WILLIAM C. BALLARD, JR.

Assistant Professor of Electrical Engineering, Cornell University

This is a standard book on radio telephony, the work of a recognized authority.

It is accurate, simple, clear, reliable and strictly up to date.

The man with a technical background who wants to post himself on radio will find this exactly the book for his purpose.

The radio enthusiast will find in it an excellent presentation of fundamental principles and their application.

truth about filament controls

FIL-KO-STAT (CURRENT INCREASES PERFECTLY AND GRADUALLY) LIKE THE RISING SUN

Electronic flow in vacuum tube depends upon filament heat. This heat varies as the square of the current. The least variation of filament heat has a great effect on electronic flow and upon reception. Wire wound rheostats cannot provide the fine adjustment necessary for filament control. Inferior filament controls are scarcely better. The Fil-Ko-Stat is distinctly designed to utilize the great tuning possibilities of the vacuum tube. It gives absolute control of electronic flow and permits the finest tuning possible. Fine adjustment of fractional currents makes it ideal for dry cell tubes; infinitesimal control of electronic flow gives fine adjustment so very essential in DX. It is non-microphonic, absolutely silent. Its fine adjustment starts where tube begins to function, at full-on resistance is practically zero. A definite off indicates complete A Battery disconnection.

NO DISCS TO BREAK OR CHIP

Resistance element so finely divided, further division impossible. Fil-Ko-Stat, compact in size takes little space on panel, replaces other control without redrilling.

GUARANTEED

The Fil-Ko-Stat is to all purposes "fool proof." Each instrument is packed with the maker's guarantee that it will be replaced if broken within one year.

The Broadcasters-Composers-Producers Muddle

THE royalty drive directed from several vantage points at the broadcasting statons of the country goes on, aided by a lot of publicity for all hands. Everybody concerned, outside the radio field, seems to have developed an insatiable appetite for royalties.

George Schubel, executive secretary of the Radio Broadcasting Society of America, charged that the American Society of Composers, Authors and Publishers had cast a "funeral pall upon all broadcasting activities."

James J. Foley, president of the Society of Radio Artists and Audiences, an organization supplying talent for radio programs, declared the music writers had taken an "unpatriotic, unsportsmanlike and purely commercial attitude."

J. C. Rosenthal, secretary of the composers' organization, said: "It is going to be the absolute ruin of the music publishing industry if the radio men do not recognize our copyrights."

These developments followed the refusal of WJZ, Westinghouse station, to take out a license.

Officials of the Radio Broadcasting Society of America are quoted as saying that there was not a chance of their compromising.

Several radio clubs, who have remained anonymous up to date, have started a boycott and passed resolutions to the effect that "under no condition whatsoever shall any member for any reason buy any sheet music, phonograph records or piano rolls controlled by the American Society of Composers until they withdraw the fee laid upon the broadcasting stations of the country for broadcasting any of their compositions."

Arthur Hammerstein announced last week that the Producing Managers, New York City, have taken up the subject of radio broadcasting and have appointed a committee of which he is chairman to look into the subject of royalties for the use of compositions now current on the stage as radio material. "The sale of sheet music and records," he said, "is likely to be harmful to patronage since they are permanent fixtures in the home and are available for reproduction at any time. On the other hand, the broadcasting of the music through the air is a transitory operation that is calculated only to whet the appetites of those who hear it for more of the same."

Representatives of 60 broadcasting stations from twelve states met at Chicago last week, organized the National Association of Broadcasters, and prepared to press an effort to prove their right to broadcast copyright music. Radio concerts, they assert, have been "dry" for the past few weeks because all the popular songs were barred. The broadcasters maintain they make no money but give the music much free advertising. They say they will carry the case to the Federal Supreme Court on this basis if necessary. Thorne Donnelly of Chicago was elected President of the organization.

To many anxious inquirers: RADIO WORLD has no free list. One copy is sent as a voucher to each advertiser or advertising agent represented in current issues. All other copies are paid for on subscription or through the news trade.

The Convenient Multi-Jack—How to Make it

By Arthur S. Gordon

SOME amateurs exercise all degrees of ingenuity when it comes to fastening the cord tips of two or more head phones together. Most of them, however, are content with a makeshift arrangement which must be disturbed every time an extra pair of phones is inserted in the hookup, while others are always at odds for a short piece of wire with which to make a temporary splice. If they are lucky, the splice will hold good for the evening, but experience demonstrates that this rarely happens. The usual result is that one of the listeners suddenly finds himself cut off from the concert, or all the listeners are annoyed with heavy and constant clicking of which there seems to be no explanation. The need for perfect connections where all the phones are joined together is just as imperative as the same need elsewhere in the circuit. To insure these connections, and to lessen the trouble oftentimes experienced, the multi-jack arrangements described in this article are presented for construction.

The devices can be very easily put together from standard parts, with very little workbench experience. They may be made to accommodate three or four headsets, or even five, if it has been found by experience that your set will operate that number.

Two designs are shown, one for the convenience of amateurs who do not employ jacks and plugs, and the other for those who do. The first design (Fig. 1) shows a piece of bakelite or panel material of any kind 1½ inches by 4½ inches, upon which are mounted four single circuit jacks. The jacks are connected in series, and come in the circuit from left to right. That is to say, unless a pair of phones is plugged in on jack No. 1, jack No. 2 is inoperative. Both these jacks must be occupied before No. 3 becomes operative, and so on.

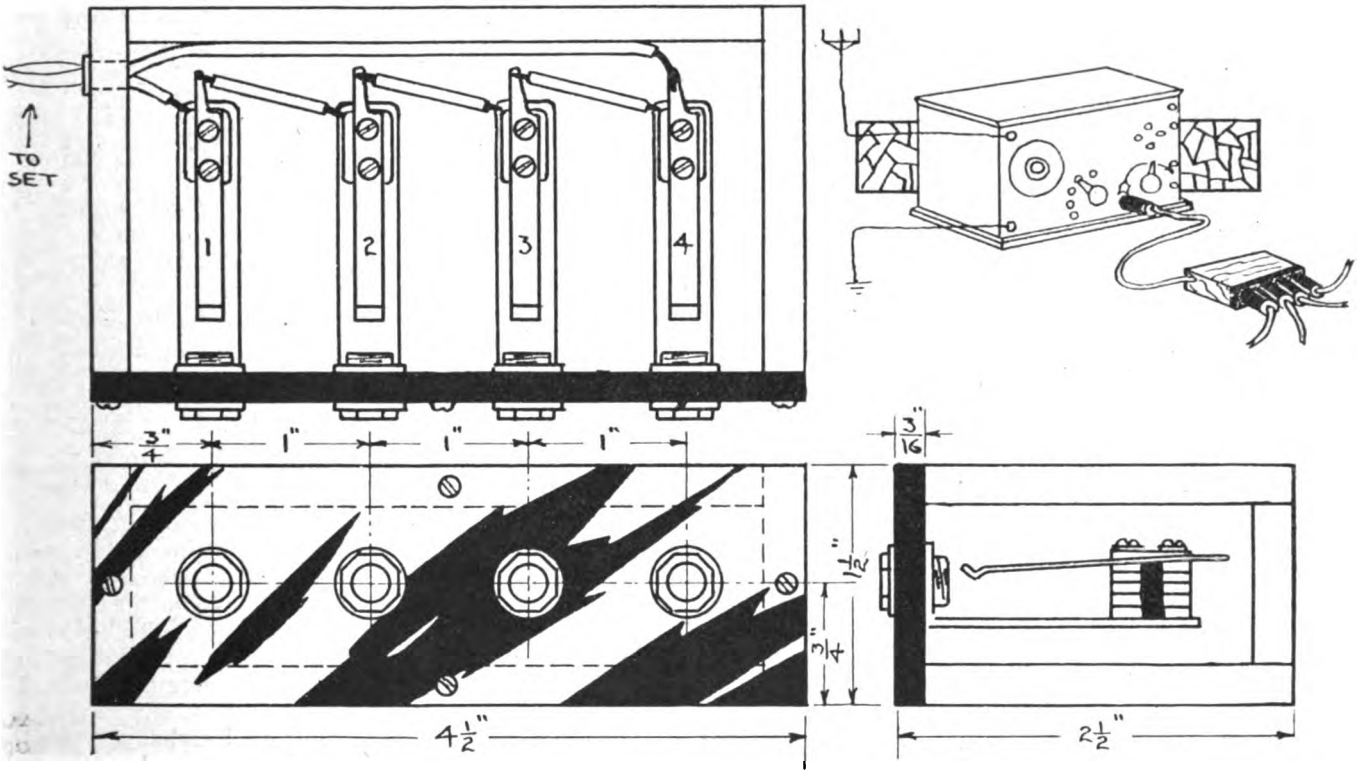

Fig. 1. Layout for making a multi-jack to accommodate four headsets.

All the connections are soldered and the whole instrument is enclosed in a neat polished wood box. The leads are brought out through a hole in one end of the box, and are fastened at the other end to a plug, which is used in the set proper as though attached to a single pair of head phones instead of to a multi-jack. Lamp cord is excellent wire for this connection, and it need not be very long.

New Wave Lengths For Class A Stations

By Carl H. Butman

WASHINGTON, D. C.—Six Class A stations, the first of the newly classified broadcasters, were licensed during the past week by the Radio Section of the Department of Commerce. Texas, Oklahoma, Illinois, Pennsylvania, Louisiana and Indiana each received one station with a wave length exclusive for its respective district.

From the schedule of wave lengths for Class A stations, printed below, it will be seen that at least twenty distinct wave lengths in each of the nine radio districts are available for distribution by the local inspectors. Three or four wave lengths in each district will be reserved for the best of the local stations of this class, these waves not being assigned to stations in the immediately adjoining districts. This gives the better of the A broadcasters a partially exclusive transmitting wave. For example, the wave length 222 meters may be assigned to stations only in the 4th, 5th and 8th districts; similarly, the wave of 233 meters will be authorized for use only in the 2d, 5th and 7th districts, while waves 224, 226, 229, etc., in column two, will be allocated in every district. This plan, it is believed, will tend to prevent considerable local interference, and create virtually an "A-1" class of stations within the general A class.

District radio supervisors, as they are called, are assigning Class A waves now, but the transfer of B stations from 400 meters will not be made until noon on May 15.

In the distribution of 582 broadcasters by districts on April 1, the 9th, the largest, including the states of Indiana, Kentucky, Wisconsin, Illinois, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, Kansas, Colorado and the upper part of Michigan, is seen to be in the lead with 190 stations, followed by the 8th, which includes lower part of Michigan, Ohio, West Virginia, and largest parts of New York and Pennsylvania.

The distribution of broadcasting stations in the Nine Radio Districts as of April 1, 1923, is as follows:

Dist.	1	2	3	4	5	6	7	8	9	
Class A...	27	19	37	31	65	63	56	71	183	—Total 552
Class B...	1	5	4	2	3	4	1	3	7	—Total 30
Total	28	24	41	33	68	67	57	74	190	—Total 582

Most of the stations designated here as A are now operating on the wave length of 360 meters, but will be placed in Class C on May 15 if they desire to continue on 360 meters.

Class A Broadcasting Wave Lengths

Frequency. kc/s	Wave Lgths. meters	All Dists.	Dists.	Frequency. kc/s	Wave Lgths. meters	All Dists.	Dists.
1350	222		(4-5-8)	1190	252		
1340	224			1180	254		
1330	226			1170		256	(1-3-6)
1320		227	(1-6-9)	1160	258		
1310	229			1150	261		
1300	230			1140		263	(2-5-7)
1290		233	(2-5-7)	1130	266		
1280	234			1120	268		
1270	236			1110		270	(4-7-8)
1260		238	(1-3-6)	1100	273

Six New Class A Broadcasters Licensed

Call	Station	Frequency kc/s	Wave Lengths Meters	Power Watts
KFFZ	Al. G. Barnes Amusement Co., Dallas, Texas	1330	226	20
KFGD	Chicakasha Radio & Electrical Co., Chickasha, Okla.	1210	248	20
WABA	Lake Forest College, Lake Forest, Ill.	1130	266	100
WABB	Lawrence, Dr. John B., Harrisburg, Pa.	1130	266	10
KFFY	Pincus & Murphy, Inc., Alexandria, La.	1100	275	100
WRAF	Radio Club, Inc., Laporte, Ind.	1340	224	10

The above stations were licensed during the week ending April 20, 1923, by the Department of Commerce and will start transmitting on their respective lengths at once.

(*Concluded from preceding page*)

The second design (Fig. 2) is for use with cord tips only. Amateurs who prefer plugs, of course, cannot use this device. It consists of a bakelite strip one inch wide by 5⅜ inches long, with two end pieces (made either of wood or bakelite) screwed or bolted

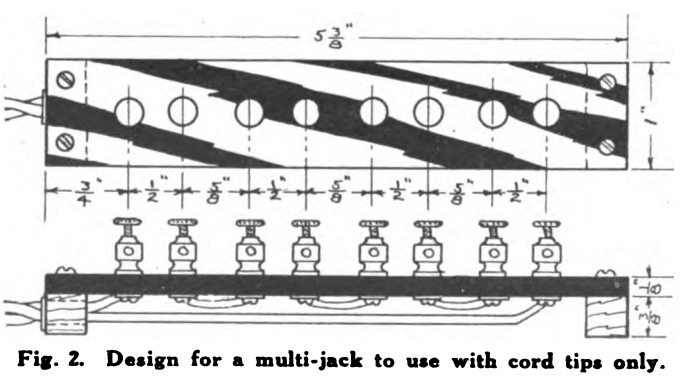

Fig. 2. Design for a multi-jack to use with cord tips only.

on. Standing upright upon this strip are eight binding posts, set apart in four units of two binding posts each. The connections are made as indicated in the drawing, and terminate either in cord tips or in a plug. Perhaps this second design, with its leads fitted to a plug, is the more economical if not the neater of the two multi-jacks submitted. Amateurs who build either of these devices will find their time and money repaid in a very short time by greater convenience and less annoyance

The multi-jack may be fastened either to the table or not, according to the wishes of the builder. It is better, perhaps, as a loose instrument, for often on a crowded operating table it can hang down below the table top where it will take up no room and yet is easy to get at.

The paramount advantage of the multi-jack is the ease with which a pair of phones may be inserted into a radio circuit or withdrawn from that circuit. Incidentally the cord tips of the phones do not become frayed from constant binding, and there is a noticeable increase in all around efficiency and convenience. For the amateur who constantly keeps two or three and sometimes four headsets in the circuit, this device is indispensable.

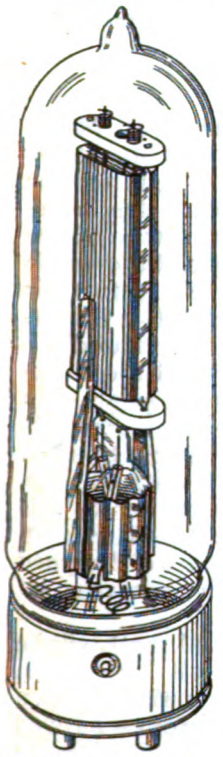
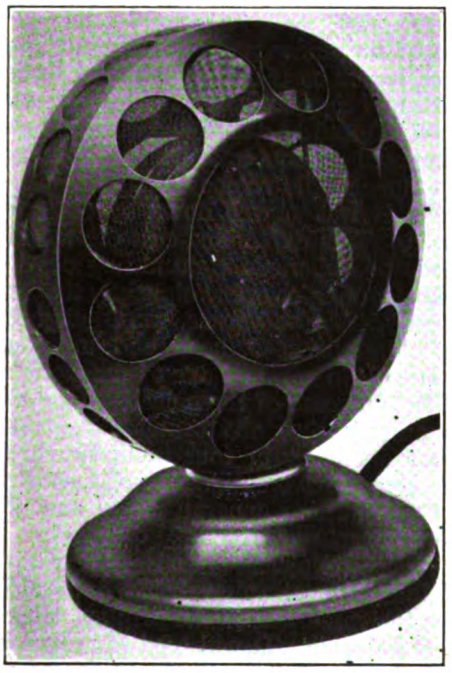
WHAZ, Rensselaer Polytechnic Station, Broadcasts Both Entertainment and Instruction

ONE of the radio broadcasting plants which has established many enviable records is WHAZ, the radio station at Rensselaer Polytechnic Institute, Troy, New York.

The equipment was installed primarily as a part of the lecture and laboratory equipment in the course in communication engineering which is given at the institute, and was not primarily meant for the regular broadcasting work as it is utilized today. The apparatus had been installed in units, in such a manner that each could be adjusted and corrected as a separate unit, without relying upon any of the other apparatus. When this apparatus was originally installed it was found that with small additional cost, it would be possible to combine both the regular routine work and public broadcasting. This course was determined upon.

When the first actual program for this station was proposed, it was the intention of the operators to use mechanical music, such as player pianos and victrolas, but the demand was found to be so great for really interesting programs, that a regular broadcasting schedule was laid out and programs similar to the other stations were promulgated. The original purpose of the station was to test fading and directional effects and this was carried on by means of outside reports with the aid of many thousands of listeners as well as the occasional research expeditions of the students and professors.





(C. Western Electric)

Figs. 1 and 2. On the left is shown a 50-watt tube such as is used on the transmitter at WHAZ. The condenser-microphone, shown on the right, is one of the latest developments in the field of microphones, embodying the carbon-disc or grain principle.

The broadcasting apparatus consists of a Western Electric 500-watt transmitter and receiver for monitoring purposes, a regulation spark transmitter, a continuous wave Colpitts oscillator circuit transmitter, which is used as a small power telephone transmitter for short work and also as an instructional set for experiments in the laboratory.

This station has been heard in Lakeport, California, a distance of 2,500 miles air line, which is somewhat of a record for a station that started out as an educational feature of this most up-to-date institution. For this last reason it is somewhat different from the usual broadcasting station, as it is used not only for the purpose of entertainment for the outside world but also as a means of practical instruction in this latest of arts, the theory of which is studied as a part of the college routine.

When the station was first opened it was decided to run test programs on the second Monday of each month; but after serious thought, and in cooperation with the popular desire, it was found necessary to put on a regular program, utilizing student talent in the form of orchestras, glee clubs, lectures and general information, such as might

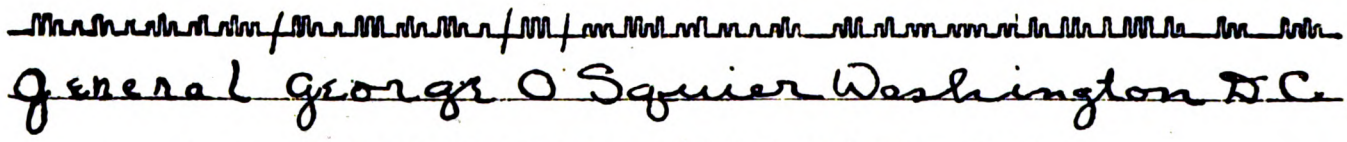
Gen. Squier Invents New Alphabet for Radio Telegraph and Cable

Will Increase Transmitting Speed Nearly Three Times

WASHINGTON, D. C., April 25, 1923.—A new telegraph alphabet for use in radio telegraph and cable in all languages has just been given to the world by Maj. Gen. George O. Squier, Chief Signal Officer of the Army and one of America's most prolific electrical communication inventors. With his new code system a speed 2.65 times the present transmitting rate can be achieved, and it is easier to "tune to."

The first presentation of this new "universal" code was made yesterday afternoon by the General in a speech before the National Academy of Sciences in Washington.

The present telegraph alphabet was invented by Professor Morse in 1844 before the telephone, alternating arc or radio transmission, and yet, with advances in nearly every other phase of communication we have continued to use the same alphabet which, it was pointed out by General Squier does not fit. It was for this reason that General Squier "redesigned" the 80-year-old alphabet for 1923 use. In the old alphabet the dots, dashes and spaces required different time for transmission, whereas the new plan provides for sending each in the same space of time. In his system in alternating current, no consecutive signals



Sample record of telegraph message as recorded by General Squier's new alphabet.

It now appears that the code used for almost 80 years will be superseded throughout the world with a gain of over 150 per cent in speed.

Briefly, General Squier proposes to vary the amplification or intensity of each half cycle of alternating current to send a dot, space or dash each of which require the same time of transmission. The signals are distinguished in receiving by the three different amplitudes, one each for the dot, dash and space. Six permutations are possible with the three intensities; one arrangement being to represent the dot with a certain intensity, the dash with a larger one and the space with a smaller amplification. The method tried successfully by General Squier in the Signal Corps laboratories was with the dash the largest, the dot intermediate and the space the smallest. Other methods will be tried, however, and a better arrangement may be found.

The system has been studied by radio experts of the Army and Navy who, it is reported, find no "bugs" in it; on the contrary they see added efficiency, and decreased interference. It is the plan of the inventor to submit the system to the next International Technical Conference of Telegraphy, with a suggestion for unification of all codes, radio, wire and cable, using the same system of modulation for the signals.

are of the same sign, but different amplitudes. In Morse such letters as S and H required three or four signals of the same sign and were not as legible as the signs for the letters A and N where no two signs were alike, they being composed of dots and dashes. The several letters of the old alphabet did not have the same legibility and the whole alphabet was slowed down by the "slow" letters to their speed. This defect has cost the world hundreds of thousands of dollars in transmitting costs, it is estimated.

In forming the new alphabet, the letters used most frequently, like the vowels, were assigned short signals. In the old alphabet O the second important letter in English, next to E in use, was one of the worst and longest to send, being composed of three dashes, requiring 11 units of time, counting dashes and spaces. General Squier sends this important letter in four units, nearly three times as fast. We should have designed our alphabet before we designed the transmitting apparatus it is now thought, whereas we worked backwards.

The new alphabet is easier to learn, it is said, and will be of international value, being applicable to all languages. The increased use of the printing telegraph makes it even more valuable. It will tend to reduce interference as well as atmospheric through the ability of receiving stations to tune in both high and low frequencies, experts believe.

(*Concluded from preceding page*)

be found interesting to outside listeners. These first programs awakened such a decided interest throughout the entire country that it was definitely decided to continue the programs and even enlarge them to meet the popular idea and demand. This has been done and several of the original features of the station have been changed to accommodate the public.

Probably one of the most novel features of this college station is the fifteen-minute talk every Monday evening on an educational subject, such as might prove helpful and interesting to the radiophone listeners.

At the time of the reception of this station in California, a fan was giving a radio party to the brotherhood of his church. There were 150 present, the great majority of whom had never "listened in." The reception from this particular station was amplified by a Western Electric loud speaker in connection with a power amplifier, and the entire program was audible from start to finish, in the 50x90 hall, in which the California party had gathered.

"PWX Is Easy Using This Circuit and One Tube"

The Stockelberg "Pup" Circuit

By Robert L. Dougherty

IN these trying times when every "ham" who owns a receiver nearly breaks his neck—or his set—to get distance so many circuits pop up that it is impossible to even keep track of them, much less give them more than a cursory trial, before something else jumps up and demands to be tried out.

A circuit recently perfected by Mr. Stockelberg, a prominent Boston amateur, is so simple to construct and easy to work (it has only one control) that it is a crime for even the most hardened fan to pass it by without giving it a trial. And if he just gives it a trial he will be convinced that it is "a real circuit."

The arrangement is described as a reversed Hartley circuit, which is an adapted Armstrong single circuit

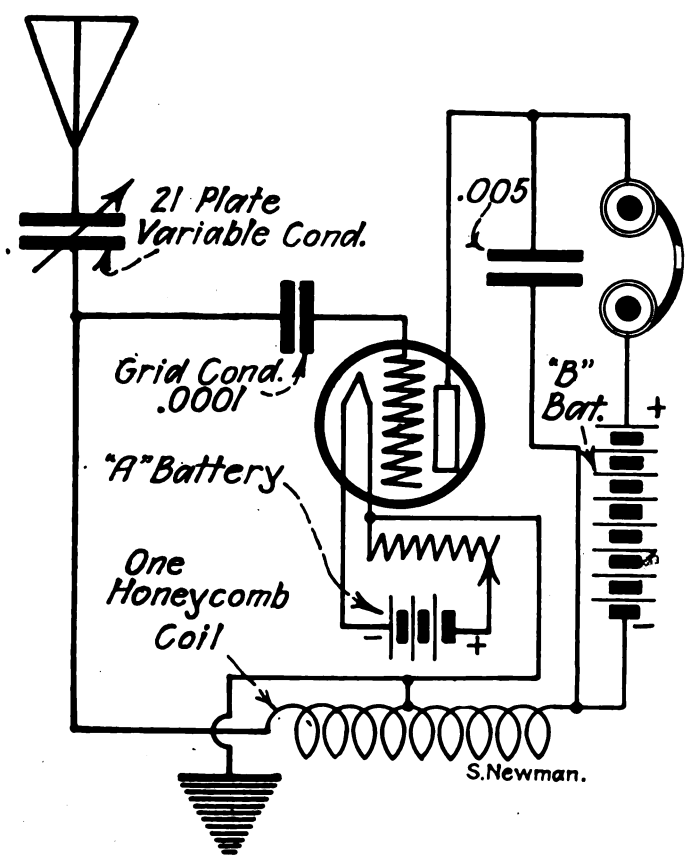

Fig. 1. The "Pup" circuit. Note that the honeycomb coil is tapped. The correct point for this tapping is explained in the text.

with several improvements which make it surprisingly selective and wonderfully sensitive. As can be seen from the diagram, a D-L 75 honeycomb coil is used. In the drawing it appears to be tapped in the center, but such is not the case. It should be tapped at about the twelfth turn, in a 75-turn coil and about the eighth or ninth turn in a 50-turn coil. It is not necessary to use the same size coil, as coils up to 150 can be used, tapping them about two-thirds of the way, as this seems to be the governing factor in the circuit. A little experimentation in that way will determine the best point, as when it is once discovered it does not have to be changed, and the lead can then be soldered on.

The tuning is accomplished by the 21 plate condenser which is located in the antenna circuit. This is the one and only tuning control and, for best results, should have a vernier button on the panel of the type that sets outside the periphery of the dial. The

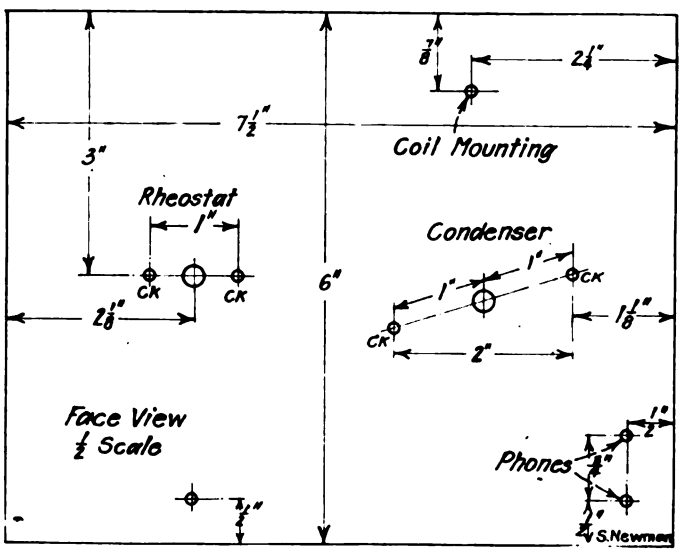

Fig. 2. Panel layout with all measurements. The panel is small, because the apparatus is arranged to take up little space, and there is only one control.

panel for reasons well known to anyone who has used a single regenerative circuit should be well shielded with either tin or copper foil, taking care that it does not short any of the leads. In order to eliminate any

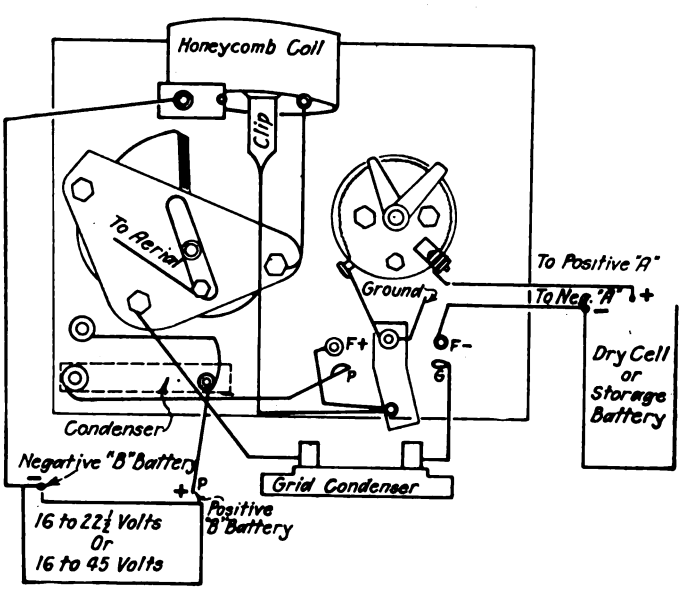

Fig. 3. How the apparatus should be mounted on the back of the panel with wiring diagram repeated for the benefit of those wanting to know how to arrange wiring.

other trouble, connect the rotor side of the variable to the antenna side of the circuit when hooking up.

The elements needed for this new and popular cir-

Radio and the Woman

By Crystal D. Tector

A VERY good friend of ours who recently acquired a reflex loop set wanted to take it across town to her mother, who is very ill, and unable to get out of bed. Not having a car, she put it in the perambulator and then, to assure herself that it was not broken, she turned on the tubes and of course was gratified to hear it working. The loop she stuck on top of the hood, after first turning the hood down. She had gone about a block when the set jogged and the battery made connection and started talking. As luck would have it she was at that time just outside a school and all the kiddies, who were going home, stopped, looked, listened, and started in to follow her, begging her to turn it on again. Some grown-ups seeing the crowd of boys following, sheep-like, followed too, just bursting with curiosity and begging her to turn it on. She became so embarrassed she said she felt that her face must have been burning up and she almost started to cry, when one woman approached her and said: "My, my, isn't that a novel way of advertising radio? My dear, will you bring one like that around to my house tonight? Maybe John will buy one, when you demonstrate it." She said she was never so embarrassed in all her life, but when she visited the woman and explained, the woman asked her if she didn't think it would be a good idea to equip some perambulators like that and try and sell radio sets by that sort of demonstration. Well, all I think is that some people just fall into luck.

* * *

Friend Husband brought a very distinguished Japanese student home the other evening and told me that he was studying law in his office, preparatory to taking a course in international law at one of the big universities. Of course we showed him our radio and to our surprise, he started in to tell us how far advanced his own country is in that particular line, saying that his father had endowed a college in Tokio for the express purpose of radio research work. He talked very interestingly for some time. I had thought that Americans were the only people who knew anything of importance connected with radio, until I met him. He actually talked like a college professor, warming up to a lecture on advanced science before a class of post-graduates. He was worth hearing.

Wouldn't it be grand if you could actually call up your favorite broadcasting station and ask to have your request number played? And also, wouldn't it be grander yet if the bootleg tubes would work as well as the regulars—or last half as long?

* * *

I notice in all the pictures I see of broadcasting studios that the singers and actors appear in costume. This puzzled me at first. What does it matter what they wear as long as their audiences can't see them? I have decided, however, that actors and singers are so accustomed by long training to "dress the part" that they might not do as well if they failed to wear costume. In this case, at least, "atmospherics" are a good thing.

* * *

The other day I read where a woman was suing her husband for a separation, charging cruelty. Her contention was that he came home, ate his supper, rushed up to the garret where he had a radio set and sat three until all hours of the morning. She said that she had forgotten that she had a husband at all, except when she had to wake him up in the morning. Well, I cut the piece out of the paper and laid it alongside of F. H.'s place so that he would see it when he came home for supper. He walked in and was all beaming, as he told me that I ought to have heard the story that one of the fellows told him in the train, coming home. It was the same story that I had cut out of the evening paper. "It's too bad that that poor Gump didn't think quick enough when he was putting in his set, to put it in the parlor, so that his 'disgusted darling' would have gotten the bug and been as interested as he was." Well, all I can say is that some men have brains and others just part their hair.

* * *

Don't you think that she is foolish? I do. I think that if I had been in her place, I would have done one of two things. I would have invited him to bring his set downstairs, or else I would have climbed up to the garret with him, and when the steam went down I would have shivered so much that he would have taken compassion on me—if radio leaves that in your system—and gone downstairs.

Radiograms

WOAW, the new $55,000 radio station of the Woodmen of the World, is broadcasting regularly from the roof of the nineteen-story W. O. W. building in Omaha, Neb.

* * *

The telegraphers' unions are discussing the possibility of establishing a "Morse Day" throughout the United States on which to honor the inventor of the telegraph and have suggested that the day be April 27.

* * *

George Hill Lewis, assistant to Powel Crosley, Jr., president of the Crosley Manufacturing Company, Cincinnati, home of radio broadcasting station WLW, is the owner of the first government license issued to a wireless operator. It was granted to Mr. Lewis in 1911.

* * *

The appointment of George K. Burgess as Director of the Bureau of Standards has been announced by Secretary Hoover, after a conference with President Harding. Mr. Burgess has been Chief Physicist of the Bureau and will succeed Dr. S. W. Stratton, who resigned several months ago to become President of the Massachusetts Institute of Technology.

Experiments made by Nebraska Wesleyan University based on thunderstorm reports furnished by the Weather Bureau are reported to lead to the conclusion that there is no relation between barometric pressure and audibility. A nearby thunderstorm area tends to reduce the audibility at the receiving station.

* * *

WSY, the broadcasting station of the Alabama Power Company, at Birmingham, Ala., sends out return postal cards with a request for comments by those who have picked up features on its programs. Over 1,000 letters were received from every State in the Union praising the singing of the male quartette of Tuskegee Institute, broadcast by WSY.

* * *

Dr. Schuyler Skaats Wheeler, inventor, engineer and physicist and President of the Crocker-Wheeler Company of New York and Ampere, N. J., died suddenly at his home in New York City on April 20. Dr. Wheeler was famous for his inventions of electric appliances, drives and motors. He was the designer of the "C. & C." motor, the first manufactured small motor for practical power work in the world. Dr. Wheeler was the organizer and founder of the United Engineering Society. He bought in Europe and brought to this country the Latimer Clark library, the largest collection of rare electrical books in existence, and presented it to the American Institute of Electrical Engineers, of which he was a past president.

Elementary Instruction for the New Army of Radio Beginners

Constantly Used Terms Explained in Simple Language for the New Radio Enthusiast

By Lynn Brooks

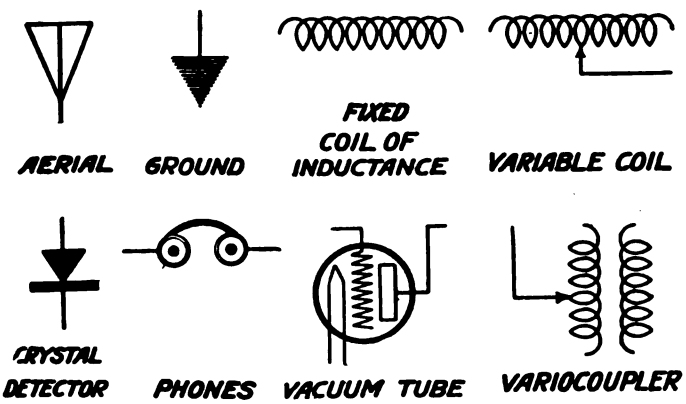
TUBE-DETECTOR: A rectifier which depends upon the theory that a heated filament in an enclosed exhausted space, will emit negative electrons. These detectors, or tubes, contain three elements—a plate, grid and filament. In short the theory is as follows: A positive charge is put upon the plate by means of a high voltage battery connected to it. The negative electrons emitted from the filament will, by nature, follow a path across the grid to the plate. This grid is alternately negatively and positively charged, by means of the condenser in the grid circuit. When it is negatively charged, it forms a screen to the electrons emitted from the filament because negative poles reject or repel each other. When this condition exists in the tube, no signals will be heard in the phones. The condenser when positively charged, changes the polarity of the grid to positive which allows the electrons to pass and carry one-half of the cycle over to the plate, causing signals to be heard on the phones.

PLATE: One of the elements in the tube detector. Generally it entirely encloses the other two elements of the tube. It is made of nickel composition. In small power tubes and detector tubes there is no oxide on this plate, but in the larger tubes handling currents up to 1,000 watts the plates are coated with an oxide.

GRID: A spiral wire enclosing the filament and situated between the filament and the plate, acting as a gate to allow the electrons to flow, or stopping the flow, depending upon the condition of its polarity.

FILAMENT: A fine tantalum, tungsten, or platinum wire which is heated by means of a battery. In the old style tubes these filaments are not coated; but in the latest models both the 6-volt and the 1½-volt tubes have an oxide coated filament which does not need to be heated to extreme incandescence in order to operate the tube at its maximum. Some of them operate at such a low temperature that the filament is not brought beyond a very faint cherry red glow. This is because in coating the filament with an oxide a greater electronic emission is provided for a given amount of current than could be had by using a bare wire. This wire is extremely thin and fine, often being no greater in diameter than a human hair. They are about one inch in length in the 1½-volt tubes, or about three inches long in the other tubes, doubling back and forming an inverted V in appearance in the larger tubes.

PHONES: A means of making the received signals audible to the ear is necessary in a receiver. To accomplish this certain apparatus is necessary, and this we know as the phones. Phones, or telephones, are composed of a case, either metallic or of some composition, within which are two high resistance magnets, the poles of which are permanently magnetized. The magnets themselves are wound with thousands of turns of very fine wire, No. 40 being generally used. Of course the many thousands of turns that are necessary, make the resistance of the magnets very high. It is a mistake to consider a phone in terms of resistance. It would be better were they considered in terms of ampere turns. Across the front of these magnets, and separated by a very small space, is a thin piece of iron or steel which is magnetized and drawn



Symbols used in drawings and illustrations to designate the different parts used in radio circuits and sets.

toward the magnets whenever a current of electricity flows through the magnets. As the rectified signal is only one-half of the phase of the received signal, the current flowing through the magnet is consequently intermittent, allowing the magnet to attract the diaphragm and release it some thousands of times a second.

DIAPHRAGM: The diaphragm of a phone is a thin circular piece of steel which fits over the rim of the phones and is separated by a minute distance from the pole piece of the magnets. Its vibration, caused by the current flowing through the magnets, allows the received signals to be heard.

Washington, D. C., to Get Another Broadcaster

THE Chesapeake and Potomac Telephone Company announces that by May 15 Washington, D. C., will have another broadcasting station. It will probably be a Class B station with an individual wave length which will reach to all corners of the nation. This company, which is a part of the American Telephone and Telegraph Company, has started the erection of the second of the Bell System broadcasting stations, and plans to duplicate in power and quality the New York station WEAF.

A unique feature is that the new plant will be a public service station; that is, it will be operated without profit and may be leased or chartered by other interests for periodic broadcasting at a rate equivalent to the proportional cost of operation.

It is understood that a local broadcasters' association may be organized and the operating time of the station scheduled to care for its members. This, it is believed, will save small operators considerable money in comparison to the costs of installation and upkeep of private broadcasting stations. Certain hours of any schedule would be reserved by the telephone company for the transmission of matter of public interest such as presidential addresses, congressional debates and governmental information. Important concerts broadcast from WEAF in New York may be sent by land line to Washington and broadcast simultaneously from the new station, officials say.

The electrical equipment is the product of the Western Electric Company, and will be installed under the direction of C. & P. and A. T. & T. Co., engineers. The station will be located on the telephone building, 725 13th Street.

Naval Radio and Aircraft More Necessary Than Gun Elevations

TECHNICAL experts are arguing whether or not, under the Arms agreement, the gun elevations of the American first line battleships may or may not be increased, when what we really need is radio and airplanes. In order to increase the range from around 21,000 yards to 24,000 yards several degrees of elevation would be necessary, but with this increase neither the gun pointers nor the lookouts on the masthead could see where the shells fell. Airplanes with radio transmitters are the only means whereby battleships can fire with any degree of accuracy over 22,000 yards or about eleven nautical miles. Radio-equipped airplanes are also of great service under that range, especially in the case of a smoke screen which would make a target invisible from the ship itself.

Due to the curvature of the earth, a rangefinder in a fighting top about a hundred feet above the surface of the sea, can observe the water line or horizon approximately eleven miles distant, which is the resulting limit of accurate fire if he does his own spotting. That is, if the observers endeavor to tell the gun captains below how much short or over the target their shots fall or how far to the right or left, eleven miles is the maximum range.

For fighting top observations over this range much taller masts would be needed or airplanes which can spot by radio. To see the water line at 30,000 yards a fighting top would have to be 170 feet aloft—too high for practical purposes by many feet. Of course, a masthead lookout a hundred feet above the sea could see the mast and perhaps the superstructure of a ship over the horizon, but he could not see the fall of the shells in the water or their splash, and would only be able to tell if the mast or superstructure were hit, which would not aid the gun pointers in picking up the target.

It is for this reason that airplane spotters which can ascend several thousand feet, are used in the Navy and it is only by radio that they can report to the gunners the exact spots where the shells fall, thus enabling them to correct their aim.

What we need as much as gun elevating, some experts think, is more naval air spotters radio-equipped.

(*Concluded from page 7*)

cuit are so limited in extent that any fan ought to find most of them right in his shop. Then, with an hour-and-a-half's time, he should have a "pup set" set up and bringing in the DX. The bill of materials follows:

Bakelite panel, 6x7½x¼	$1.50
1 3-inch dial	.50
1 Vernier button-panel mount	.20
1 Vernier rheostat	1.25
2 Brackets—1 large—1 small	.23
4 lengths bus bar wire	.20
1 Grid Condenser, .0001—No leak	.75
5 Binding posts	.25
1 Condenser, .001 fixed	.25
1 21 plate condenser	1.50
1 DL-75 Honeycomb coil	1.62
1 Single mount for Honeycomb coil	.60
1 Socket for tube	.75
Total	$9.60

Additional apparatus, if no tubes or batteries are on hand:

1 Dry cell tube	$6.50
1 A battery	.40
1 B battery	1.50
1 pair of phones	5.00
Total of entire set	$23.00

This set, when made up for the newcomer in the radio field, or the old "hard-tack," does not cost a mint of money, and at the same time is sensitive enough to satisfy the most hardened DX Nite Owl, in his hunt for freedom and the open spaces.

The panel layout for the set is given herewith, and all dimensions are all worked out completely, so that the prospective builder should not worry about details. Drill your holes carefully, being sure to make the holes for the condenser from a template. If you do not get a template with the condenser, do the following: Take a fairly stiff piece of paper, or a card, and make a hole in the upper center of it, of sufficient size to accommodate the shaft of the condenser. Then with a pencil, find and pierce a hole for each of the standards of the condenser, taking care that the card or paper is held perfectly still, and does not move. Then use this as a template, by pasting it on the wrong side of the panel, and drilling through the center of the marks you have made.

A back view of the panel is also given to show the location of the various pieces of apparatus, as laid out for efficiency and short leads. Extreme care should be taken in the wiring, making sure that you run the wires correctly. Too much care cannot be taken in wiring a set, and ten minutes spent tracing the wire after you have finished may save a disgusted builder and probably a burnt out tube. Note the fact that there is no grid leak used in this circuit.

Consider that you have built the set, wired it up, and are ready to listen in. Turn on your tube about three-quarters and turn the condenser toward zero. If the set is functioning properly, the click or squeal of regeneration will be heard and, if a station is operating, the carrier wave of the station will be heard. Using your vernier button on your condenser, tune between the two squeals, and if the voice comes in muffled, turn down the filament battery a bit. This may cause the signals to die out entirely, and if such is the case, turn up the rheostat, one notch at a time, until the squeal is again heard. Then turn down just one notch, and bring the vernier of the rheostat into play until the voice or music is plain and unmuffled. Then leave it entirely alone, and do all your tuning with the condenser for the rest of the evening, unless the battery runs down. Then you will have to tune with your vernier rheostat again.

If when you are tuning in you do not get the set to function properly, try another tap on the honeycomb either nearer the center or further away, always one turn at a time. When the right spot is found, as before stated, solder it, and leave it alone, because it will remain the same unless a different antenna is used.

This set has been tried and found true. It works on an antenna 40 feet long and only 25 feet high with remarkable selectivity, even though ten stations could be brought in within 10 degrees. Because of the fact that it is so simple to construct and operate it should prove extremely popular. The only trouble that can be experienced is that of tapping the honeycomb coil, and that cannot really be called trouble if care is taken in doing it.

Navy Electrician Designs Efficient Four Tube Transmitter

A VERY neat, compact and efficient transmitter has recently been made by M. Bebaut, chief electrician at the Radio Center, Navy Headquarters, New York City. The circuit employed is the original Colpitts oscillator, using grid modulation. With this set distances of 1,800 miles have been covered constantly on CW, and 900 to 1,200 on phone and buzzer modulated CW.

Referring to the diagram of the circuit published herewith, it will be noted that the four tubes (CW-931 5-watt tubes) are hooked in parallel, as to plate and

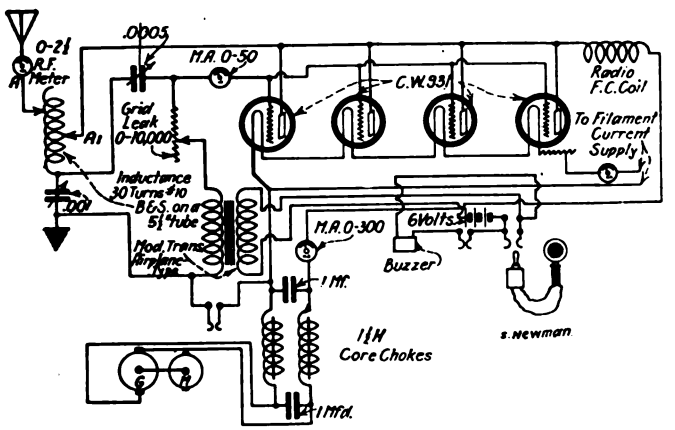

Fig. 1. Hook-up of circuit used by Chief Electrician Bebaut.

grid, and the filaments are all in series. The current for the filament is taken directly from the 110-volt line, using four 60-watt bulbs in series-parallel, in series with a 6-ohm rheostat, in the positive lead on the tube side, for finer regulation of the filaments.

The current from the plates is derived from a standard Westinghouse Electric motor-generator unit which delivers up to 550 volts to the plates, through two 1½-henry iron core chokes, with two 1 mfd. condensers at either end to remove the ripple. The motor of this unit is driven from the 110-volt line, through four 100-watt bulbs in series-parallel.

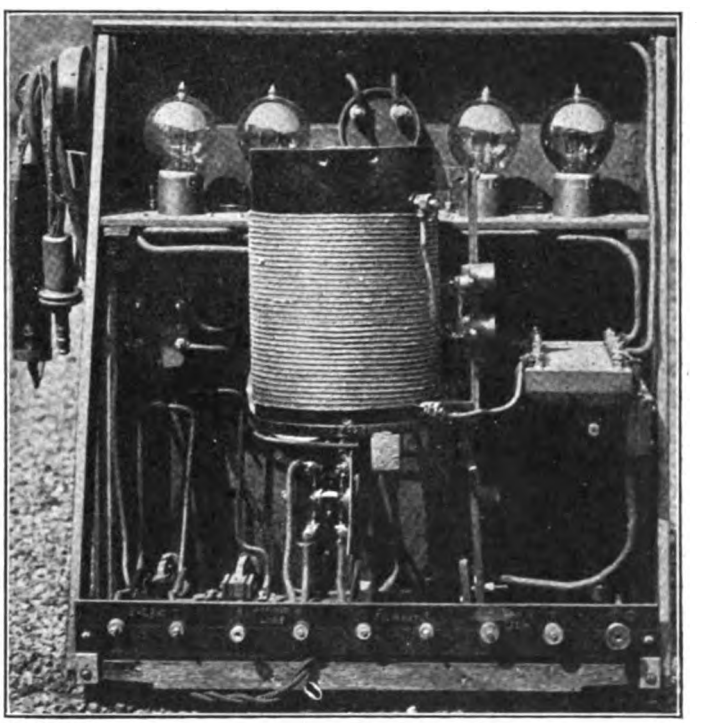
The modulation of the set is accomplished through a modulation transformer in the grid circuit, the secondary of which is in series with the 0-10.000 ohm leak of the non-inductive type. This transformer is the airplane type commonly used now on all of the U. S. Navy destroyers, on their intermediate wave sets. For CW the key is inserted directly between one leg of the generator, which goes to the filament side, and the grid side of the circuit, as illustrated. This has been found to give the best results as concerns the space current when using straight CW, because there is less fluctuation at the break and make of the key.

An important part of the set is the tuner, which as shown consists of 30 turns of Brown & Sharpe No. 10 insulated wire on a 5½-inch core. The important part of this tuner is the fact that the two sliders for antenna and plate tuning are attached to one another, approximately 5 to 7 turns apart, and they are both tuned together. On the antenna tuning switch is a piece of metal, which shorts the rest of the coil that is not being used, doing away with the dead-end effect, and at the same time giving much sharper tuning.

When it is desired to use the set in phone work the plug is inserted in the extreme right hand jack. The jack immediately next to it is for buzzer modulation, and the key is inserted in it for ICW.

An air core choke coil is inserted in the plate lead of the last coil. This choke is necessary to keep the plate circuit from backing up and down when fluctuations in the plate circuit occur.

The other illustration shows a comprehensive interior view of the set as well as all the apparatus and the controls. When the set was planned it was thought necessary to have a wave change switch to allow transmission on 150 meters; but when this was attempted, it was found that the change meant that the



(C. Photonews.)

Fig. 2. Interior view of Chief Electrician Bebaut's four-tube set.

whole tuning would have to be readjusted, so it was dropped and transmission on 200 meters was set.

The antenna used for this set is a six-wire cage antenna T type, 50 feet in length and 32 feet in height, situated at the extreme lower end of New York City in the U. S. Naval Communication Bureau's Office. With this set which is rated at 20 watts, using four 5-watt CW 931 tubes, stations in St. Louis have been consistently worked. Stations in South Carolina have picked up this station on both CW and ICW and once reported receiving phone for a short period.

Coming! New List of Broadcasters!

While the Department of Commerce has assigned wave lengths for each of the broadcasting zones established by the recent Second National Radio Conference, individual assignments of station wave lengths have not been announced. They are being arranged as rapidly as possible and as soon as finished A COMPLETE, UP-TO-DATE LIST OF BROADCASTERS will be published by RADIO WORLD.

The allocation of wave lengths for Class A stations appears elsewhere in this issue of RADIO WORLD.

Developments of Vacuum Tube Research

By F. S. McCullough

Research Engineer, Westinghouse Electric & Mfg. Company

A PERSON using a vacuum tube seldom realizes that this tube is not a development of recent years. It has a long history back of it. The forerunner of a vacuum tube was the experiment of Edison in 1883, when he observed an electric current between the plate and a hot filament in a vacuum. Simultaneously some German scientists were working on it. The work of Edison was followed by Preece, Fleming and Thompson, English scientists. It was not until 1899 that Sir J. J. Thompson suggested an explanation of this phenomenon. About this time Marconi introduced radio telegraphy. Sir J. A. Fleming applied the vacuum tube for detecting radio signals in 1904. In 1905 DeForest, the American, changed this vacuum tube. The new tube was able to amplify the signals. Then in 1913 E. H. Armstrong invented an electric circuit, which with this tube was capable of producing oscillating currents suitable for sending radio waves or regenerating received signals. By regenerating we mean multiplying these signals hundreds of times. This briefly is the history of the tube you are using.

Larger tubes of this type are used at the broadcasting stations. For transcontinental telephone transmission, telephone companies are using a similar tube. In appearance, it looks somewhat like an electric light bulb. It has a glass bulb for maintaining a vacuum. This is sealed in a metal base. Mounted inside the tube you can see a heated filament surrounded by a complicated metallic structure. A radio engineer would tell you this was the grid and plate, and if you examine carefully, you will see that the outside of the structure is a thin metal plate formed into a cylinder or an oval. Between this plate and the filament, you will see a wire coil or a mesh. This is the grid. Now imagine a stream of electrical particles shooting out from the filament and across the space through the grid to the plate. This grid acts like a door. By opening and closing this door you can vary the amount of current that goes through; only you open and close this door electrically, and not mechanically. Just like a small child can open a door for a grown up person, so can the small electric currents open a door for large electric currents. That is exactly how a vaccum tube works.

To produce this tube, the scientists and engineers had to solve quite a number of technical and scientific problems. Years of research and millions of dollars were spent on developing the materials, the methods and the machinery for the manufacture of these tubes. To give you an idea of what these problems are let us compare the vacuum tube to an electric light globe. In the latter we have a vacuum which has about one-millionth of ordinary air. In a vacuum tube there is ten million times less air than in an electric light globe. Imagine the trouble of getting this vacuum. When you get nearly this far, the glass walls and the metal parts inside of the tubes begin to give off gas. Before vacuum tubes were invented, the scientists did not even know that the glass and the metals could contain gas. Now they had to find a way to remove the gas, and make sure no more gas would come out after the tube is in service. It may be interesting to observe that with all this vacuum an average receiving tube will still contain about ten to twenty billions of atoms of gas.

You have seen tubes with a bright filament and a dim filament. Some need a storage battery while others will burn with a dry cell. It is seldom realized that dry cell tubes take only one twentieth as much power as a storage battery tube, yet give the same service. However, a large amount of experimental work had to be done before this small amount of power could be made to do the work. The engineers had to develop a filament of extremely fine dimensions. This filament is one fourth of one-thousandth of an inch thick and ten-thousandths of an inch wide. This means that it would take four thousand of these filaments to make up on inch if laid side by side. This filament must be then coated in a delicate manner with a layer of active material. When you consider that it must be mounted in the center of the coil one-sixteenth of an inch wide, you will get some idea of what the difficulties are. The other extremes in vacuum tubes are the power tubes at the broadcasting stations. These tubes are made at the present time in sizes which range up to 1000 kilowatts. This means that they are capable of delivering about 1300 horsepower of radio energy to an antenna. Of course, no broadcasting station is now allowed to use such an amount of energy. When this will be allowed one broadcasting station will be able to reach the extreme ends of the earth. This day is not far distant. A few years from now you may be able, on your set, to listen to one station in London and another in Pekin.

Warning Against Fake Radio Inspectors

A "FAKE" radio inspector has been issuing "licenses" to amateur and boradcasting stations in Minnesota, the Department of Commerce has been advised. Using the return stub of an amateur application blank secured from the department, an individual giving his name as Cecil Osborne is said to have supervised the installation of a radio station in Minnesota and issued what he called a license.

This impostor claimed that he was a former radio operator of the Navy Department and a member of the Naval Reserve. The only record of a man of that name in the files of the Navy Department, is that of a deserter who served for a time as an apprentice and seaman. He deserted in San Francisco in July, 1922, the official records state.

All radio inspectors of the department, the officials in Washington point out, are supplied with means of identification, including official badges and identification cards bearing their photographs. Amateurs and broadcasters are advised to ask for identification cards and to pay no fees for licenses. Although the White Radio Bill contemplated the payment of fees for licenses, it failed to pass. The present law provides for the licensing without charge.

OUT-OF-PRINT ISSUES OF RADIO WORLD

TO RADIO WORLD readers who want copies of our issues of April 22, May 20, June 24, Oct. 21, and Dec. 2:

These issues are out of print. If you have any copies of these dates and will send them to us, we will send you current issues for them. If you have ordered any of these issues from us, please let us know if you wish to have us return the money to you, or send you current issues.

How to Make a Built-up, Sectional Aerial Mast

By Arthur G. Shirt

AMATEURS who live in isolated buildings are often confronted with the problem of how to hold up the far end of their antenna. There are no trees or other buildings conveniently near, and a pole or mast of some kind seems to be the only way out of the difficulty. The expense involved in buying and erecting a mast of suitable height cannot always be met; moreover, there is always the problem of transporting a ready-made structure of lengthy proportions. These considerations are often the only reasons why some radio fans do not own their sets, and it is to help them that these plans for making a really ingenious mast from a few lengths of 2x4 studding are here presented.

The mast in question stands 36 feet high. It may be

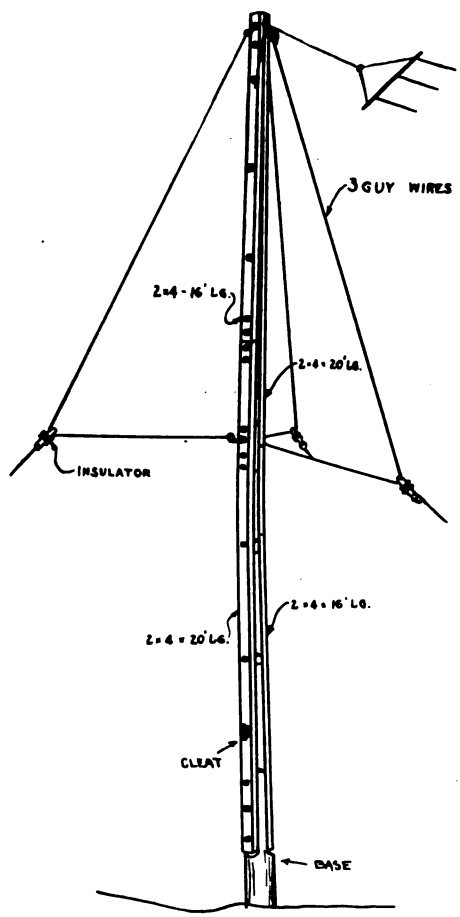

Fig. 1. Sketch of mast as it should appear when erected. It is guyed in the manner shown, which eliminates the necessity of using many guy wires.

extended to any greater height up to the reasonable limit of from 60 to 70 feet. It is easy to make, easy to raise, and once up, is guyed so that it will stay up. Its sturdiness is beyond question, yet it is neither heavy nor bulky. It has been designed for the special use of radio amateurs, and has been tried out successfully in a number of cases. A careful study of the accompanying sketch will reveal the many desirable features of this built-up, sectional mast.

It is made of the following materials: A fence post eight or nine feet long by eight inches in diameter; four lengths of studding, two pieces 20 feet long and two 16 feet long; a number of insert blocks of varying thickness; six closed hooks for the guy wires; a pulley, or block, and three insulators. To this list of articles may be added three turnbuckles to keep the guy wires taut.

The fence post is buried about five feet in the ground. It serves as the base for the mast. After being well embedded it is dressed down with an ax for about three feet of its upper portion, the dressed part being five inches wide. This rectangular head serves not only as a pivot about which to elevate the mast, but also as the initial in-

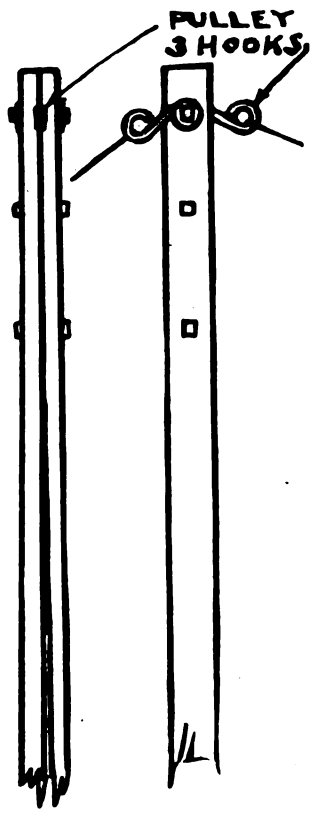

Fig. 2. Method of attaching guy wires to hooks.

sert block. In the case of a 36-foot structure as shown, the width of the mast at the bottom should be about five inches. As the mast increases in height above 36 feet, however, this block should be made wider, so that the entire structure keeps its proportion. Three bolt holes are drilled in a vertical line as shown in Figs. 1 and 2 and the spaces left between these holes are later duplicated upon the lower part of the two joints which are used for the bottom section of the mast.

The second insert block is 4½ inches wide. There are seven blocks in all, placed about as shown in Fig. 1, each tapering slightly and decreasing in width as they near the top. Note that the third and fourth insert blocks are at

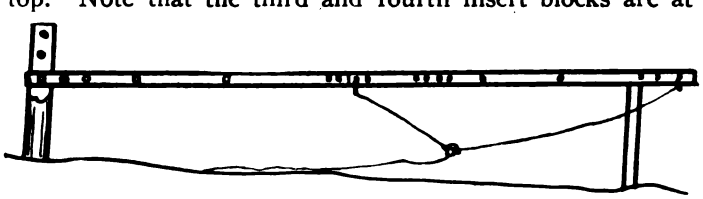

Fig. 3. Attach the guy wires before raising the mast. Then, when it is up, slip the necessary bolts in place, tighten and pull in on the guy wires by means of turnbuckles, making sure that the tension on each wire is the same.

the joints, and are therefore longer than the others. Also note that the joints are made on opposite sides and the mast is so assembled that they are six feet apart. This feature of the construction is an essential one, since it adds

Important Meeting of Radio Interests Discusses New Wave Lengths, Royalties and Price-Cutting

NEWARK, N. J., April 26.—Matters of interest to both dealers and manufacturers were discussed at a joint dinner-meeting of the Radio Manufacturers of New Jersey and the Radio Trade Association held at the St. Frances Hotel tonight.

President LeFevre, of the Sheltone Company, in opening the meeting outlined the purposes of the New Jersey Manufacturers' Association and spoke of the great interest and enthusiasm already shown by the members, though this was only the fifth meeting of the association.

Mr. C. B. Cooper of the Crosley Manufacturing Company, Cincinnati, who is a member of the Hoover Wave Length Commission, was the principal speaker of the meeting. In a very concise way, Mr. Cooper outlined the work of the recent Commission meeting held in Washington. Mr. Cooper praised the fine spirit of cooperation shown by all those present, especially by the government broadcasting officials, who agreed to broadcast on lower wave lengths. Two hundred to six hundred meters being the common wave length of broadcast reception from now on, the task of the manufacturer will be a great deal easier. Mr. Cooper also read the new allocations of wave lengths for broadcasters in the New York or Second District of the Department of Commerce.

In discussing the difficulties of the broadcasters with authors', publishers' and other associations that insist on royalties from broadcasting certain matter, Mr. Cooper voiced the opinion that the broadcasters may be forced into an association either to fight such antagonism or to publish their own songs and the like.

Selling radio in the home was the theme of the sales talk given by Mr. H. C. Gawler of the Radio Corporation of America. Mr. Gawler showed that the same methods that have sold phonographs and vacuum cleaners will sell radio sets. He emphasized the fact that the woman is the one who must be sold if the dealer wants to sell apparatus into the home.

Mr. W. H. Harkness, of the American Telephone & Telegraph Company, New York, told of the work of his broadcasting station, WEAF. Mr. Harkness said that the endeavor of his station was through research and constant study to give those programs that the people actually wanted. To do that, his company maintains a broadcasting staff of approximately fifty people. The operating staff consists of twenty, the remainder of the organization being occupied in the work of studying the matter that was broadcast.

Mr. D. W. May, of Newark, N. J., Station WBS, discussed some of the difficulties that his firm had become involved in with the authors' and publishers' leagues.

The vital subject of price cutting was taken up by Lawrence A. Nixon of the Radio Dealer, when as secretary of the Radio Trade Association he spoke of work of that association. It was at the suggestion of Mr. Nixon that the joint meeting was called. Mr. Nixon praised the work of the trade association that has just been formed in New York to combat the evil of selling goods on a cut price basis.

The subject of price cutting occupied most of the attention in the informal discussion that followed the main addresses.

Among those present were: Mr. Bryant of the Chicago office of L. S. Brach Company; Mr. Morton of Clapp-Eastham; Mr. Salzman of the Wholesale Radio Equipment Company, Newark, N. J.; Mr. Lynch of Radio Broadcast, and Mr. Friedman of Radio World.

New Wave Lengths For Second District

At a meeting of the broadcasters of the New York (Second) District with Radio Inspector Batcheller on April 24, the following wave lengths were assigned, to go into effect May 15, 1923:

Meters	Call	Station
233	*	Radio Shop of Newark, Newark, N. J.
244	WBAN	Wireless Phone Corp. of Paterson, Paterson, N. J.
263	WSAP	Seventh Day Adventist Church of N. Y.
	WAAN	I. R. Nelson, Newark, N. J.
273	WRW	Tarrytown Radio Research Laboratory, Tarrytown, N. Y.
	WFAF	H. C. Spratley Radio Co., Poughkeepsie, N.Y.
360	WQAO	Calvary Baptist Church, New York.
	WBS	D. W. May, Newark, N. J.
	WLAW	New York Police Department.
	WHN	Ridgewood Times, Ridgewood, L. I.
	WNJ	Shotten Radio Mfg. Co., Albany, N. Y.
405	WOR	L. Bamberger & Co., Newark, N. J.
	WJY	Radio Corp. of America, Aeolian Hall, N. Y.
	WDT	Ship Owners' Radio Service Co., New York.
455	WJZ	Radio Corp. of America, Aeolian Hall, N. Y.
380	WGY	General Electric Co., Schenectady, N. Y.
	WHAZ	Rensselaer Polytech. Institute, Troy, N. Y.
492	WEAF	Amer. Tel. & Tel. Co., New York.
	WBAY	Western Electric Company.

* Not yet known.

Because it is a duplex station, the new Radio Corporation of America's station on top of Aeolian Hall, New York, was assigned two wave lengths.

(*Concluded from preceding page*)

too much to the strength of the mast to be omitted with safety. The best material for the studding is straight-grained yellow pine, two inches by four inches.

The insert blocks are first nailed in place and then bolted with ⅜-inch carriage bolts. Fourteen of these bolts are needed in all. This is not counting the three bolts at the foot of the mast, which are of ½-inch stock. The other hardware consists of six closed hooks, three of which are fastened to the top of the mast, either as shown in Fig. 3 or as required by the particular make of hook employed. The other three hooks are placed midway down the mast at about the first joint, and three bridles are made with the guy wires as shown. Three strain insulators are placed at the head of these bridles and the main guy wires taken from them. The main guy wires are then anchored to stakes or to weights embedded in the ground, and tautened by means of turnbuckles.

When everything is ready for elevating, lay the mast out on the ground with the yoke fastened loosely to the base by a single bolt. Straighten out the guy wires and leave them in charge of helpers, who spread out and keep the tension even as the mast rises. Two men with forked clothes poles can raise it easily. Have some one ready to put in the two bottom bolts as soon as possible, for when these are in, however loosely they may be inserted, the mast cannot fall. When the guy wires are taut, raise the aerial, and the job is finished.

Wireless Telephone Receiving Apparatus

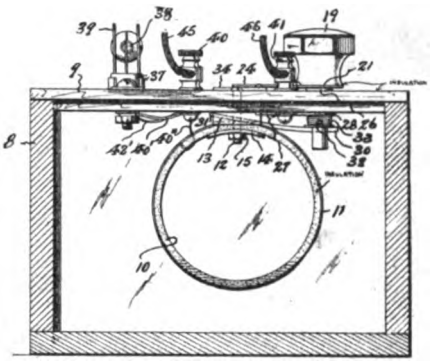
No. 1,448,287: Patented March 13, 1923. Patentee: William F. Gehrig, Newark, N. J.

THIS invention relates, generally, to improvements in wireless telephone apparatus; and, more particularly, to a novel arrangement and mounting of tuning coil and detector devices for wireless telephone receiving sets.

The invention has for its principal object to provide a novel and simple arrangement and mounting of cylindrical tuning coil together with a novel rotary slider switch for cooperation therewith; and the invention has for a further object to provide a neat, simple, cheap and efficient arrangement and mounting of said tuning coil devices together with suitable detector devices for association therewith.

Other objects of this invention, not at this time more particularly enumerated, will be clearly understood from the following detailed description of the same.

With the various objects of this invention in view, the same consists, primarily, in the novel tuning coil and detector set for wireless telephone reciving apparatus hereinafter set forth; and, furthermore, the invention consists in the novel arrangements and combinations of the various devices and parts, as well as in the details of the construction thereof.



Sectional view of Gehrig's wireless telephone receiving apparatus.

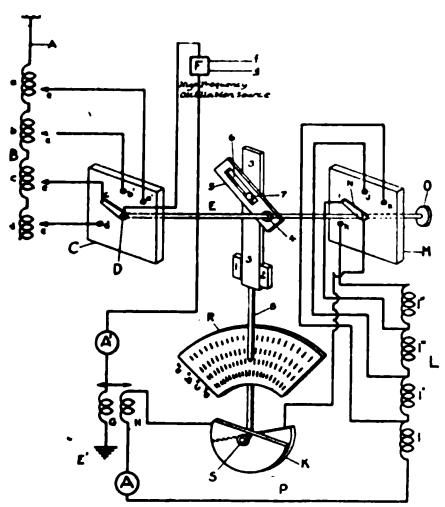
Combined Wave Changer and Wave Meter

No. 1,450,038: Patented March 27, 1923. Patentee, Guy Hill, Washington, D. C.

THIS invention relates to radio signaling apparatus, but more particularly to a wave changer device. The primary object of the invention is to provide operative means in connection with a wave changer for accurately determining the wave length of knowing the wave length transmitted after the set is once tuned and adjusted in case the constants of the antenna are changed; that is, if the set was adjusted to a fixed antenna and this antenna became destroyed, and a new antenna of different constants had to be used, the operator could in no way determine the wave length being transmitted unless he was provided with a wavemeter.

If such a set includes a wavemeter, which is a separate piece of apparatus, such an instrument might easily be removed from the set, and if the transmitting set were on shipboard the wavemeter could easily be left ashore, or in some inaccessible place so that, in case of emergency, the operator might have no method of knowing the wave length he was using.

The present invention overcomes the above difficulties by having a wavemeter built into the transmitting set as a definite part of the transmitting equipment, and, in addition, so mechanically coupled to the transmitter that when the wave length is changed the indicating pointer of the wavemeter is also adjusted to prevent the operator setting his wave-changing switch on one wave length and his wavemeter indicating pointer on the wrong scale, and thereby cause confusion.



Hill's combined wave changer and wave meter.

using a wavemeter having several scales, which are attached to the movable plates of a variable condenser.

The invention involves a method of having the indicating pointer of the wavemeter, which indicates the wave length on the various scales, so combined with the wave changer that, as the handle of the wave changer is operated, the pointer for the wavemeter is operated and picks out or selects the proper scale.

In radio transmitting sets, such as arc sets, where coupled circuits are not employed, impact sets, and certain forms of audion sets, where the radiated wave length depends upon the constants of the antenna circuit and not upon the constants of the primary circuit, the operator has no method

System of Telephony

No. 1,449,372: Patented March 27, 1923. Patentee: Harold D. Arnold, East Orange, N. J.

THIS invention relates to a method of, and apparatus for signaling by means of modulated high frequency waves or currents.

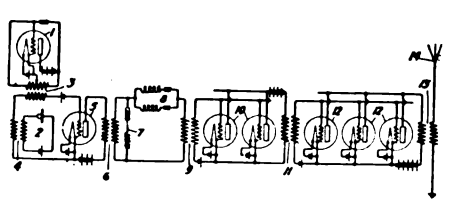


Diagram of Arnold's system of telephony.

More specifically its object is to increase the efficiency of telephonic communication by modulating a high frequency oscillation and eliminating from the antenna, or other sending circuit, constant amplitude oscillations of the carrier-wave frequency, which, in present practice, are impressed upon it. Further objects are to improve the quality of speech received and to make possible the secret transmission and reception of messages.

These objects are accomplished by providing an arrangement of circuits whereby current is suitably modulated and is supplied to the antenna only when the characteristics of the high frequency current to be impressed on the antenna are changing in accordance with the wave form of the signal to be transmitted, and by providing at the receiving station a small auxiliary generator which shall furnish a wave of the frequency of the unmodulated carrier wave.

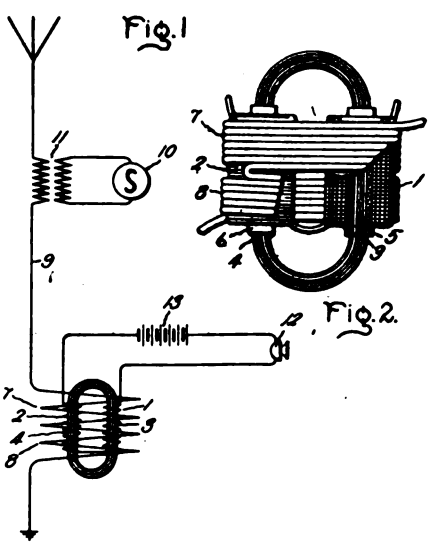
Heretofore in high frequency carrier wave telephony it has been customary to employ a generator of unmodulated or carrier high frequency oscillations, which oscillations are modulated in amplitude in accordance with the low frequency signals to be sent, and are then radiated. At the receiving station, detecting devices are used to respond to low frequency modulations only.

Modulator

No. 1,449,871: Patented March 27, 1923. Patentee: John B. Pratt, Schenectady, N. Y.

MY present invention relates to modulators of high frequency current, and more particularly to modulators of the type commonly known as magnetic amplifiers.

Devices of this general type as used in the past, described for example in U. S. patent to Alexanderson 1,206,643, have ordinarily been constructed with the closed magnetic core made up of thin laminations. They have been constructed either by first assembling the laminations of the core and then winding



Details of Pratt's modulator of high frequency currents.

the coils on this core by threading the conductor through the opening or by first winding the coils and then assembling the laminations making up the core. This latter method requires that the laminations instead of being continuous must be cut in order to permit them to be inserted within the coils.

The object of my invention is to provide an improved method of constructing the magnetic core of such a device which will be simpler than previous methods and result in an improved product. In carrying my invention into effect I first wind the coils which are to surround the closed magnetic core and then form the core by threading a thin ribbon of magnetic material through the coils making enough turns in this ribbon to provide the desired cross sectional area of the core.

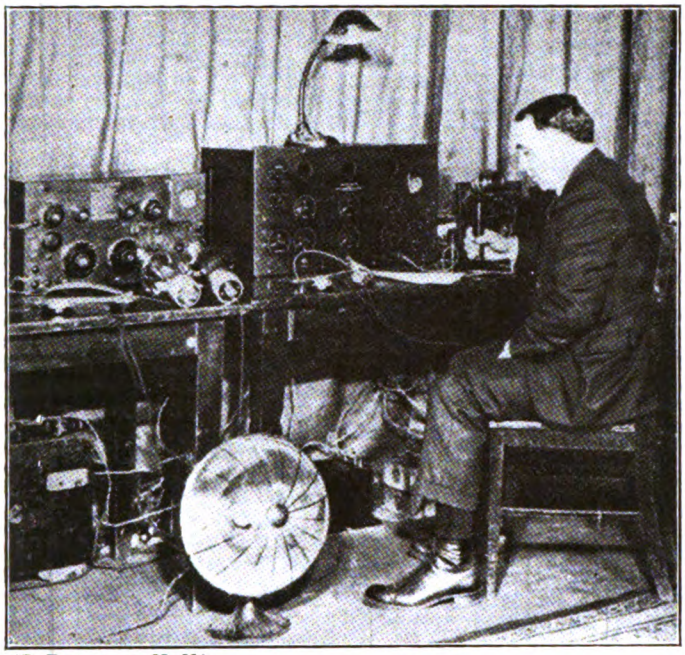
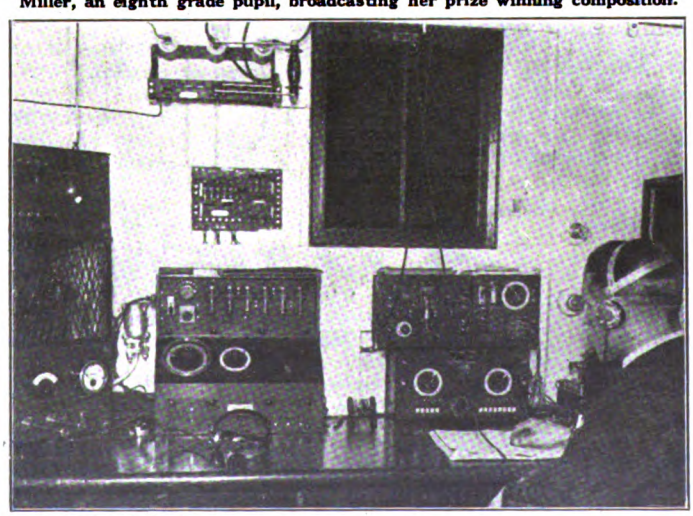
All Important Radio Events Snapped By

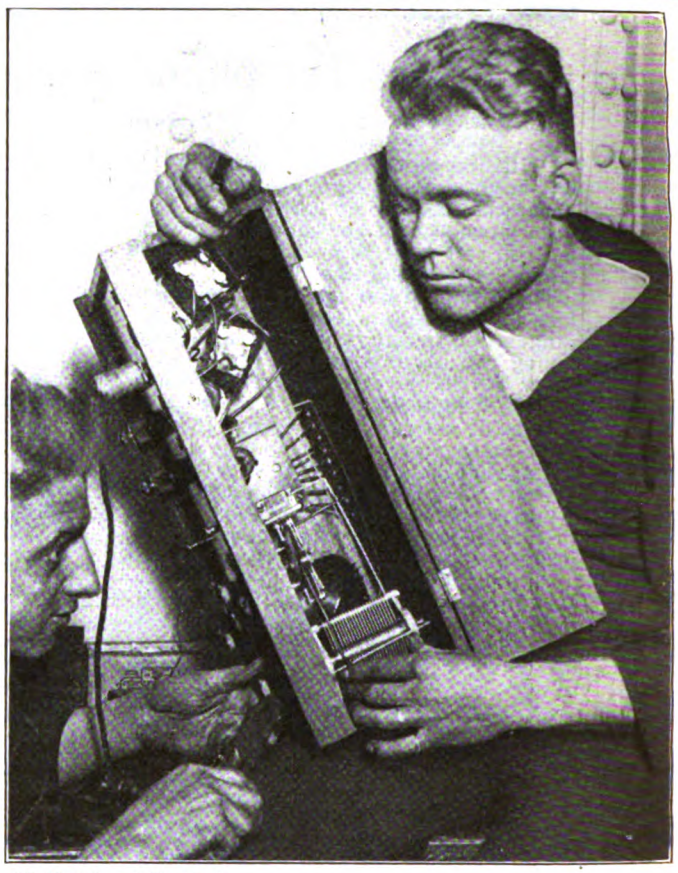


(C. Fotograms, N. Y.)
During these days of uncertain weather, when you can't tell whether the next minute is going to be cold and your bunions are paining so steadily that you can't rely on them for a barometer, the farmers are very grateful to the report service as broadcast from the market centers of the country. The above photo shows the broadcasting station at Roselle, N. J., where they send out the latest market reports on all produce and thereby keep the man on the farm "in the know."

(C. Kadel and Herbert)
A new feature that has created much interest among public school pupils and teachers is the broadcasting through their local stations. Station WHN, of Ridgewood, L. I., was the first to inaugurate this method of procedure. The pupils all compete in composition to get the opportunity of broadcasting their work through this station. The photo shows Violet Miller, an eighth grade pupil, broadcasting her prize winning composition.



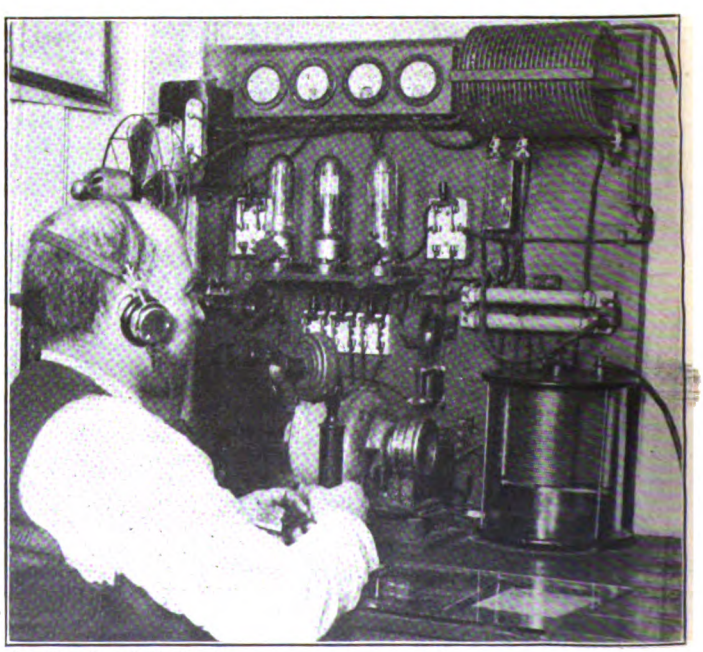
(C. Kadel and Herbert)
The radio room of the S. S. "Belgenland," the newest Red Star liner. This ship is fully equipped with high-speed transmitters and receivers which enable it to handle messages five to eight times as fast as manually.



(C. Kadel and Herbert)

Unofficial Radio in the Navy

Every one knows that the United States Navy is equipped with the most modern and powerful radio apparatus in the naval world. Nowadays they even control battleships by means of radio, fire explosives, and operate hidden mines. Because of that fact few people realize that there are many hundreds of radio fans aboard Uncle



(C. Kadel and Herbert)
150-watt transmitter of Frank Frimerman which has been heard in Honolulu and by ships in the Atlantic at the same time. The set uses three 50-watt tubes on either phone or CW. They are shown in the center of the board right below the four meters. The motor-driven chopper, used when uninterrupted CW is desired, can be seen directly next to the condenser on the right.

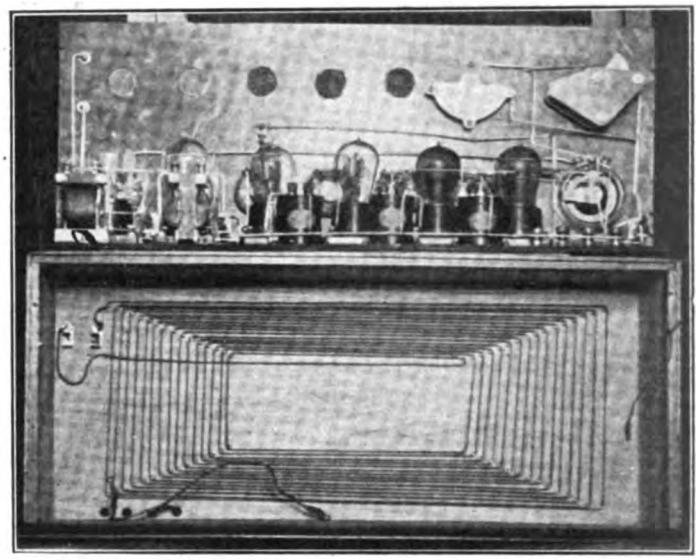
Sam's big boats, but merely consider the naval radio as something to occasionally listen to, and copy if they can.

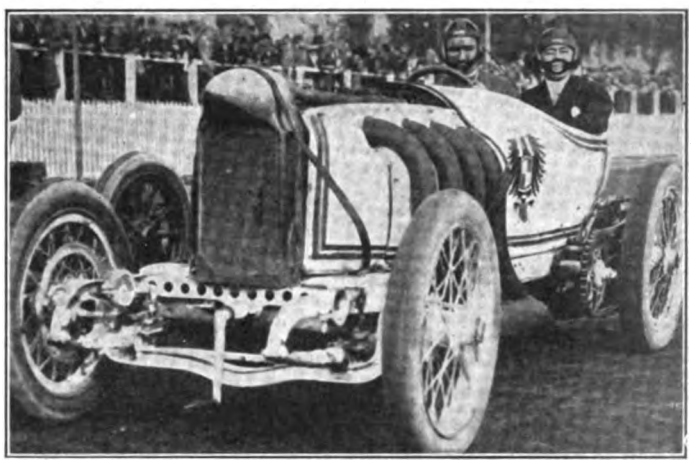
The illustrations herewith show what a hold radio has on the men in the navy. The illustration to the left shows Seamen Mummee and June with their three-tube set, which received WJZ in the Canal Zone, using the auxiliary antenna of the ship. The smaller picture above shows Lt. Commander Vanauken with his set consisting of one step of radio frequency detector and two of audio-frequency. The transformers for this set were made by the constructor and are of the air core type. They can be seen directly in front of the set.

Even though there are many constructors on board the ship, it is not always easy to get an antenna, because of the fact that Uncle Sam won't let everybody string a lot of wire around the ship, where it may be a nuisance, so therefore the boys are called upon to exercise a little bit of ingenuity in the matter of antennae.



(C. Kadel and Herbert)

Compact and self-contained receiver designed by Rutledge Mayo, of New York City. It uses three stages of radio frequency (the first three tubes counting from the right), detector, and two stages of audio-frequency. The loop is contained as shown in the cover of the cabinet. The set can be operated by simply turning on the tubes and swinging the cabinet in the direction of the desired station and tuning with the two condensers shown on the upper right hand corner. The condenser on the left is a three plate vernier, necessary to fine tuning. A 1,500-mile radius is claimed for this set, using the loop and a loud speaker.



(C. Kadel and Herbert)

Equipping fast racing autos with radiophone is the latest wrinkle developed in the radio field, utilizing the invention of Bernays Johnson which was described in RADIO WORLD some time ago. The photo shows one of the "rip-snorters" equipped with the apparatus, just after a race, in which all the sensations of riding at a mile a minute clip were faithfully reported by the man seated next to the driver. The transmitter and receivers are concealed in the helmet, and the apparatus, needing neither high voltage batteries nor generators, and the transmitter taking but very small space without the necessity of using an antenna and ground.

(C. P. and A. Photos)

The latest wrinkle for keeping the busy children of busy mothers busy while busy mother is busying around the house after daddy goes to work. It entirely supplants the rattle and rubber doll. The only precaution necessary is to see that Imogene does not get busy and chew a few yards of insulation off the wire, which is not according to the strict diet rules of the younger class.

(C. International Newsreel)

As a means of keeping the poor movie director from yelling himself hoarse when directing big scenes, they are installing loud speakers with the regulation power amplifying and speech amplifying panels and microphones. The director, instead of using a megaphone, can now speak gently into the microphone, and the actors will hear him as though through the ears of a thousand amplifiers.

Answers to Readers of Radio World

Kindly inform me where I can obtain a circuit of a two-tube reflex set using a crystal detector and a three-tube reflex set using a tube detector, with antenna and ground, and also loop. Can a loop be used at the same time as the outdoor antenna? Which is better, the crystal detector or the tube detector in reflex circuits? Should I use the same type R. F. transformers in both stages, or are different ratios necessary?—L. M. Rickersond, Laraby Place, Baltimore, Md.

If you will refer to the March 3 issue of RADIO WORLD, you will find the desired information and hook-ups on page 4, under the heading "Multi-tube Reflex Circuits," by W. S. Thompson. Fig. 1 is a diagram using two tubes with a crystal detector, and Fig. 2 is a diagram of a reflex circuit using three tubes. With these circuits you can use either antenna and ground with a tuner, or a loop. If you use the antenna and ground it is connected across the first variable condenser in place of the loop. A loop should not be used when an antenna and ground with a tuner is used. For extra volume, we suggest that when using a loop, you connect a lead from the ground to one side of the loop at the point where it connects to the variable condenser. The advantage of using a crystal detector in a reflex set is its extreme clearness and quietness of operation. The crystal detector is the most perfect rectifier of radio signals, as concerns original tone and clearness. It is a slight but less sensitive than the tube and for that reason many people prefer the tube detector, but at the same time the difference in volume is so slight that it is better to use the crystal in view of the extreme faithfulness of reproduction. Unless you intend using tuner radio-frequency, it is not essential to use different ratio transformers.

* * *

In connection with the article on the "Universal All Wave Receiver," described by F. J. Rumford in the April 7th issue of RADIO WORLD, *is it possible to use the new U. V. 201A tube, instead of the WD-11? Would I have to make any changes in the original wiring? What does the U. V. 201A cost? In using the tuner for a detector what plate voltage would be necessary, and also what is the bias voltage in the grid lead circuit?—Raymond Dabney, Harber, Texas.*

The tube you mention can be used in this circuit, with no changes other than using the regular socket instead of the WD-11 socket. This tube sells at $6.50 list. You should use 22½ volts on the plate for a detector, and 45-60 volts for an amplifier. There is no bias battery necessary—use a grid leak and condenser, as shown.

* * *

In the article published in RADIO WORLD *for January 20, 1923, by Ortherus Gordon it states that a brass rod must be used as the standard of the tickler coil. I am unable to obtain a brass rod. Will an iron rod do? —Theodore F. Fehlandt, 917 Watson Street, Ripon, Wis.*

If you cannot obtain a brass rod use a wooden or copper rod. Iron has a peculiar effect on radio signals when used in or around an inductive circuit, due to hysteresis' which would cause you to lose some of the signal strength.

* * *

I have constructed the set described by Mr. Shults in a recent issue of RADIO WORLD, *but, being within 10 miles of WBZ, cannot tune him out and get other stations with success. He operates on 422 meters. What do you advise?—M. L. Cramer, 46 Cleveland Street, Holyoke, Mass.*

We advise the use of a filter circuit embodying a honeycomb coil and .0005 condenser in parallel in the antenna circuit. Such a filter was described in RADIO WORLD for January 27, 1923, by F. J. Rumford.

* * *

I constructed the set described in RADIO WORLD *for March 10, on page 19. I note that the grid connects indirectly through the tuner to the positive A battery. The set will not function. Is this the trouble? Should it not connect to the minus?—Frank Haas, 120 East Iowa Street, Evansville, Ind.*

You are correct. The grid return should be negative, and connect to the minus side of the circuit you mention. A potentiometer would be of use in this circuit.

* * *

In your diagram of the set described in RADIO WORLD *for January 20 by Ortherus Gordon it states that the top coil (50 turn) goes to the plate and phone. Is this right, or should the 50 turn be the bottom coil?—Roland C. Hetherington, 404 Portage Avenue, Sault Ste. Marie, Mich.*

The 50-turn coil in this circuit is the primary or bottom coil, and the larger 75-turn coil is the tickler, and goes to the plate and phones.

* * *

In RADIO WORLD *for March 3, 1923, you published an article by C. White. Should the condenser C-1 be 13 plate or 43 plate? Should the "B" battery be 22½ or 45 volts? How is the copper shielding grounded?—G. D. Greneman, General Delivery, West End Station, Colorado Springs, Colo.*

This condenser should be 13 plate, as a 43 plate would have too much capacity and the tuning would be too fine. Only a very small variations of capacity are necessary to obtain regeneration and fine tuning.

The "B" battery should be 22½ volts, although using 45 would not hurt the tube, outside of making it harder to control the oscillations.

Shield the copper foil on either the ground post or the negative side of the "A" battery by means of a strip of the same foil that you are using.

* * *

In RADIO WORLD *for February 17, 1923, you published an article by M. C. Batsel on Radio-Frequency vs. Audio-Frequency. In his eighth paragraph he states that the simplest form of radio frequency without the use of addition tubes is the Armstrong regenerative. I have never seen the particular diagram referred to before, although I understand that Armstrong has several circuits. Is this particular one the super?—A. H. Cosman, 728 Royal Ave., New Westminster, B. C., Canada.*

The circuit referred to is the three circuit regenerative, utilizing a variocoupler and two variometers. Numerous hook-ups of this particular circuit have appeared in past issues of RADIO WORLD.

* * *

I am considering building the set described by C. White in the March 3, 1923, issue of RADIO WORLD. *He states that you must use a variocoupler, but does not state the size of the wire that is to be used. Will you please advise me what size wire to use, and also how to wind it?—Wm. F. Grimes, East Gloucester, Mass.*

We refer you to the Anniversary Number of RADIO WORLD, March 31, 1923, where you will find a descriptive article by Arthur S. Gordon on how to make a variocoupler, under the heading of "The Ultimate Coupler —How to Make It," on page 12. It is completely descriptive, giving all the details. This will help you out.

* * *

I am constructing the set described by Mr. Shidler in RADIO WORLD *for March 10, on page 20. He mentions the fact that the tickler coil has 50 turns of wire. Where is this coil, and where does it go? Also what is the dial above the vernier, in the center of the top row on the panel layout?—Michael Shapiro, 2834 W. 30th Street, Coney Island, New York.*

When he used the words tickler coil, he was referring to the rotor of the coupler which is used as a tickler in this particular single-circuit set. As can be seen it connects with the plate and phones, to effect feed back for regeneration. The bulb socket is located in the space you mention and he has drawn the tube in this manner with the rheostat on one side and the primary variations on the other.

* * *

We have a six-tube receiver using a loop three feet square of nine turns of No. 18 lamp cord, each turn three-eighths inches apart. Would a series condenser in one side of the loop make it more selective? We have a one-wire antenna 125 feet long, 50 feet high at one end and have tried to work it with a variocoupler, but have obtained poor results. What can be the trouble?—S. C. Olson, Pablo, Montana.

You do not state what type of receiver you are using, but from the fact that you mention six tubes, we surmise that radio-frequency is used. You should be able to get great selectivity with a loop, and it is not necessary to put the loop in series with a condenser as it will not work properly. The correct method is to shunt the loop with the condenser. Try using a flat loop, winding the wire in a square spiral instead of a solenoid. Better selectivity can sometimes be had by doing so. The set should function properly if connected to antenna and ground by a variocoupler. The secondary should connect across the terminals of the variable condenser that originally shunts the loop. More volume can be had when using a loop if a tap is taken off one of the connections of the loop and connected to the ground.

* * *

In the March 24 issue of RADIO WORLD *you published an article by C. White on the subject of combining radio-frequency and regeneration. What should be the range of such an outfit? At present I have a three-step radio-frequency detector and two steps of audiofrequency, working on a loop. Would the set described give any better reception, as concerns clearness and distance? —E. W. Moreau, 668 Meadowbrook Ave., Detroit, Mich.*

There can be no definite range set for any receiver, as there are too many conditions upon which good reception depends to actually state the range for any receiver. You ought not to have trouble getting 1,500-2,000 miles easily when you learn how to operate it properly. This distance is of course approximate and you may do much better than this, but a conservative estimate is always best when considering receivers in terms of miles.

You ought to get better results as to distance with this receiver than with your loop receiver, because an outside antenna will increase the distance. The advantage of a loop receiver is its extreme selectivity and quiet operation when hooked-up to a good circuit.

A MAGNAVOX
Power Amplifier
for your
Magnavox Reproducer

MAGNAVOX products are made for people who judge Radio equipment as expertly as the engineer judges a locomotive or a musician a violin.

To answer such requirements, the Magnavox Power Amplifier was developed for use with the Magnavox Radio, the Reproducer Supreme.

Under present conditions, the combination of Magnavox Reproducer and Power Amplifier represents the last refinement in Radio reception — a demonstration at your dealer's is the convincing proof.

R2-18 Magnavox Radio
(With 18-inch horn)

This instrument is intended for those who wish the utmost in amplifying power; for clubs, hotels, dance halls, large audiences, etc. It requires only .6 of an ampere for the field.
Price $60.00

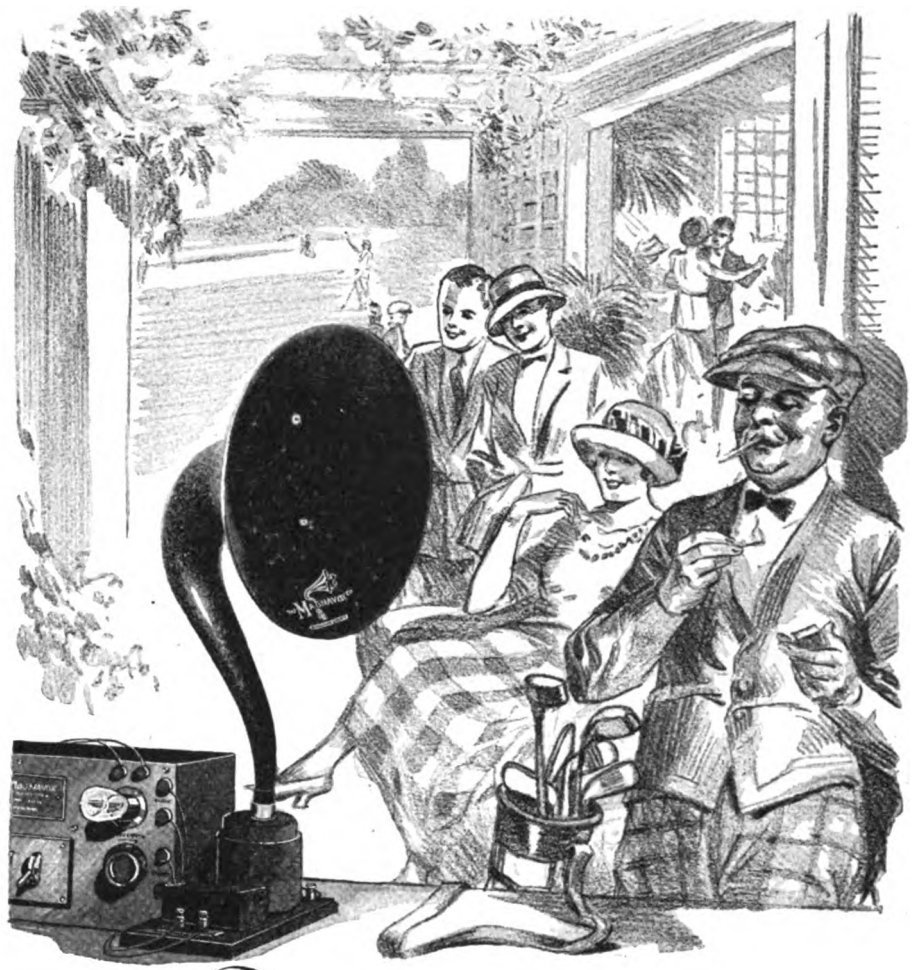
R3-14 Magnavox Radio
(With 14-inch horn)
As illustrated

The ideal instrument for use in homes, offices, amateur stations, etc. Same in principle and construction as Type R-2.
Price $35.00

AC Magnavox Power Amplifier
As illustrated

For use with the Magnavox Radio and insures getting the largest possible power input.
2-stage, $55.00
3-stage, $75.00

Magnavox Reproducers and Power Amplifiers can be used with any receiving set of good quality. Without Magnavox, no receiving set is complete.



On the Veranda *of the* Country Club

WHERE Radio apparatus, like a professional entertainer, must meet the test of satisfying really discriminating people, Magnavox is certain to be installed.

The first requisites — tone clearness, pitch and quality—are fulfilled by the Magnavox Reproducer; the addition of a Magnavox Power Amplifier supplies the other requisite, volume.

Magnavox Products can be had from good dealers everywhere. Our interesting new booklet will be sent on request.

The Magnavox Co., Oakland, California
New York: 370 Seventh Avenue

MAGNAVOX Radio
The Reproducer Supreme

Some DX Records to Shoot At

Another Miller Circuit Booster

From D. Alexander, 607 Hastings Street West, Vancouver, B. C.

AS requested by you in RADIO WORLD for October 21 in connection with the Miller circuit, wish to advise that I have been operating such a set for the past month, built according to your diagram with the exception of two minor changes. Instead of using a 50-turn honeycomb coil I find that, with an aerial of 150 feet, it is necessary to use a 75-turn coil for the 360-meter stations, and, for sharper tuning, a coil of 100 turns brings in the 400-meter stations better. I also have eliminated the grid leak.

To say that this hook-up is good would be putting it mild. I have been getting remarkable results with it, and it is by far the best I have tried in my two years of experimenting with different circuits. The signals come in with great volume, and the tuning is very simple. To give you an idea of what I have accomplished I am attaching a list of stations tuned in from February 13 to March 16. Most of these stations are received every night in the week if desired. For Madison, Chicago and Indianapolis I used one stage of amplification after tuning in, all of the others being received on detector tube alone. The mileage shown is via direct air line measured from a radio map. I have received as many as 18 stations in one evening.

For local stations the signals are so strong that I find it necessary to use only one stage of amplification to operate my Magnavox at sufficient volume to be clearly heard all over a large sized room. For distant stations two steps are necessary.

At times I use a UV-200 detector tube, but for best results a VT-1 is used. My aerial is a single-wire, L-type, 150 feet long and about 30 feet high. I find that by using a variable B battery, with switch for changing voltage, much better control is obtained. Within a space of four degrees on the condenser dial I have tuned in as many as six stations by simply turning the dial half a degree, decreasing or increasing the filament, and decreasing or increasing the plate voltage. I would strongly recommend any one trying out this circuit to use a Bradleystat. I tried out all the best known wirewound rheostats, but the Bradley has them all beat for strength of signals and clearness.

THE editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

Miller circuit as used by Mr. Alexander, with which he has done some wonderfully fine work. One improvement on the original circuit is the potentiometer in the filament leads which gives greater selectivity and control of the signals.

Come Right In, You Have Plenty of Company

From Felts Cooper, 316 Melba St., Dallas, Tex.

I AM sending you my record of stations I have heard each night on my crystal set. This set consists of a home-made loose coupler, a crystal detector and a pair of Ciessmann 3,000 ohm phones. No condenser of any kind is used in my set. My record is: WHB, WDAF, both in Kansas City; WOC, Davenport, Ia.; WOS, Jefferson City, Mo., and WMC in Ohio. I hear KSD, St. Louis, about three nights each week. I think this is a good record for a crystal set. I am working on a three-tube set and when it is completed I am going to join the DX Nite Owls. There is no powerful tube set near me, and besides I hear these stations every night.

* * *

A Little Bit of Something Else

From C. G. Montgomery, 699½ Park Place Ave., Bradley Beach, N. J.

I READ with interest the article "An Improved Single Circuit for Nite Owls," by F. N. Hollingsworth, in your issue of RADIO WORLD dated March 10. Mr. Hollingsworth talks as if it is good work for a Nite Owl to get Canada, Cuba and Porto Rico using one tube. I get WKAQ, San Juan, P. R., almost every time he is on, and could get PWX, Havana, the same but for local interference.

I received the following on detector only: WHAD, WDAF, WMAQ, WGM, WSAJ, WEAS, KSD, KDKA, WOS, WBT, WBZ, WFI, WGI, WGY, WHB, WHN, WIP, WJZ, WLW, WOC, WOO, WOR, WSB, WWJ, WAAM, WBAM, WCAE, WEAF, WFAS, WHAS, WHAV, WHAZ, CFCA, PWX and WKAQ.

* * *

Eventually, Why Not Now?

From J. J. Chapman, 3129 Holmes Ave., Minneapolis, Minn.

HERE is another record for the DX Nite Owls.

On the night of March 23, 1923, I tuned in 25 stations, with a total mileage of 17,820 miles.

The stations heard during that evening were: KFI, KGW, KSD, KYW, WAAN, WAAW, WBAP, WCX, WCAE, WDAF, WDAP, WDAR, WFAA, WGY, WHAS, WJZ, WMC, WOC, WOS, WSAJ, WSB, WSY, WLAG, BN7, 8XI.

The apparatus that I use consists of a variocoupler and a variable condenser and one tube. The hook-up is somewhat unusual, but is very simple to operate.

The farthest distance I have covered is: PWX, Havana, Cuba; KFI and KHJ, Los Angeles; KGW, Portland; WOR, Newark, and WEAF, New York.

I think that this is quite a good record for one tube.

* * *

Doing DX with a CR8

From Erwin Grau, Chicago, Ill.

I AM a constant reader of RADIO WORLD, and buy it weekly. I have noticed the column devoted to the DX'ers, and am sending in my list, which I would like to have published next week. I use a Grebe CR-8. The following is a list of my local and DX work so far:

DX—WJZ, WOR, WOO, WIAO, WGY, WOS, WSY, WBAP, WPA, WWJ, WCX, WDAF, WSB, WOC, WDAS, WOAN, WEAF, WGI, WGR, WDAK, WAAY, WLAP, WKAD, WWB, WAAK, WBAD, KDKA, KSD, WGAB, KYI, Bakersfield, Cal.; KFAD, Phoenix, Ariz.; KFAY.

Local—WDAP, WPAD, KYW, WMAQ, WWAY, WBU, W[illegible]AF.

Can Wireless Set Off a Blast?

The increasing use of wireless and radio apparatus has led industrial users of explosives to speculate whether the electrical currents released by this might not cause premature explosions when charges are connected up for electrical firing, according to the Explosives Engineer. Obviously, this is a startling line of inquiry, the answer to which will deeply interest all those who engage in electrical blasting.

The matter has been put before the electrical bureau and the radio division of the Bureau of Standards at Washington, and representatives of each expressed the opinion independently that it would be impossible for an electric blasting cap circuit to collect enough energy from a radio station to fire a cap, unless the cap circuit were less than one mile from the radio station. This opinion was based on the assumption that one-quarter of an ampere is a dangerous current.

Four-tenths of an ampere is usually the minimum current that must pass through the bridge wire to fire one cap; but this would be too weak a current to use in series because of the leakage that occurs in most circuits. The manufacturers recommend at least one and one-half amperes to the circuit when caps are connected in series, and three-quarters of an ampere per cap in parallel connection. It would seem, then, that this estimate allows a liberal margin of safety and that blasters need have no fear of radio currents one mile or more from the station. This refers, of course, to high-power stations. The small radiophones used in dwellings need not be considered.

German Radio Patents Confiscated by French

THE Interministerial Committee appointed by Premier Poincaré has decided on the immediate seizure of German inventions patented in France, the most important of which is the Meissner patents on wireless. These patents immediately will be put at the disposal of the French War and Marine departments, according to a press dispatch from Paris. The seizure is held to be justified under Article 306 of the Versailles Treaty, which gives the right "to impose such limitations, conditions or restrictions as are considered necessary for the national defense or public interest." The Meissner patents are considered of the highest importance by the Ministry of Posts and Telegraphs.

Remarkable Regenerative Receivers

Ace Model V
$20
Formerly known as Crosley Model V-t

This one tube receiver is astounding the radio world with its wonderful achievements. Stations more than 1000 miles away are being regularly copied on this set. In comparison to its price, there is no receiver on the market today to equal it in performance.

Licensed under Armstrong U. S. Patent No. 1,113,149. The trade name Crosley is used by permission of the Crosley Mfg. Co.

Live Jobbers and Dealers are eagerly taking advantage of the sales this instrument and the rest of the Precision instruments and parts bring them.

PATENT PENDING

The Niftiest Short Wave Tuner on the Market
Only $6.00 & PP on 1 lb. Send for pamphlet.

L. W. GOODMAN
DREXEL HILL, PA.

The GOODMAN is really a high grade instrument, well and sturdily constructed. The PANEL and FANS are GENUINE BAKELITE—the best material known for the purpose.

Subscribe for RADIO WORLD, $6.00 a year, $3.00 six months, $1.50 three months.

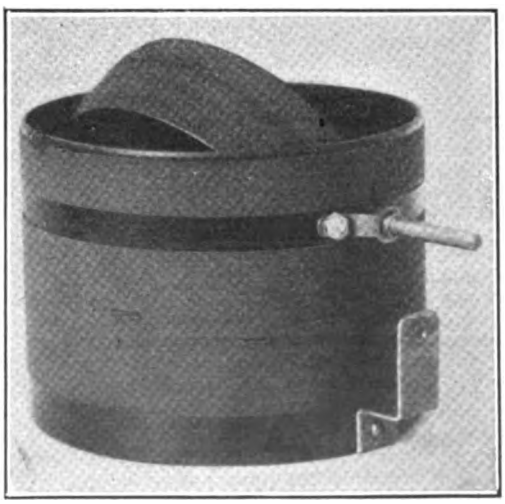
TO GET THAT DISTANT STATION

USE A COAST COUPLER

This coupler is designed along strictly scientific lines, and is the result of eighteen months' experiment. Wound with green silk covered wire on Bakelite tubing. Very selective.

Following are a few of the many DX stations received with this coupler, and detector tube only, at Long Beach, California:

PWX, Havana, Cuba
WWJ, Detroit, Mich.
WSB, Atlanta, Ga.
WDAP, Chicago, Ill.
CFCN, Calgary, Can.
WBAP, Ft. Worth, Texas



Our adaptation of a popular hook-up furnished with coupler. Coupler fully guaranteed when hooked up according to instructions.

Coupler and diagram, sold only under our money back guarantee. Mailed anywhere in the United States upon receipt of $5.00. Post Office or Express money order.

Radiall Moving to Larger Quarters

THE trade is advised that, after May 1, the main office of the Radiall Company, now located at 99 Warren Street, New York City, will be at 654 Grand Avenue, New Haven, Conn. All letters and communications should hereafter be sent to the new address.

The Hartzell Sales Co.

PRESTON M. SMITH, formerly sales manager of the Dubilier Condenser & Radio Corporation, New York City, has been appointed general manager of the Hartzell Sales Company, a manufacturers' sales organization, well and favorably known throughout the eastern and southern states. They represent some of the highest type radio accessory manufacturers, among these being: Alden Mfg. Co., Springfield, Mass.; American Transformer Co., Newark, N. J.; C. Brandes, Inc., New York City; Dubilier Condenser & Radio Corporation, New York City; H. H. Eby Mfg. Co., Philadelphia, Pa.; Electrad Corporation of America, New York City; Mu-Rad Laboratories, Inc., Asbury Park, N. J.; Tait Knob & Dial Co., New York City; The C. D. Tuska Co., Hartford, Conn.; U. S. Tool Co., Newark, N. J.; Witherbee Storage Battery Co., New York City.

The Hartzell Sales Company maintains offices at: 623 Victory Building, Philadelphia, Pa.; 705 Granite Building, Pittsburgh, Pa.; 1028 Fourth Avenue, Huntington, W. Va.; 302 Flatiron Building, Atlanta, Ga. Within a month they will open a fifth office at Dallas, Texas. The territory they cover includes, on the north, New York State (excepting the metropolitan district), west to and including Indiana, and all states south to and including Texas and Oklahoma.

The Hartzell Sales Company has a high-type, clean-cut sales policy, offering the products of the manufacturers they represent to the high-grade, legitimate jobber and manufacturer only, giving such their fullest co-operation.

Small But Efficient

The Electric Service Engineering Company, 105 West 47th street, New York City, have called their latest achievement in circuits "The Radio Pup" set. "Pup" is evidently appropriate to the circuit only because of its size and the small number of parts involved; for if the circuit does what its makers claim for it, it is certainly no junior affair.

"1,000 Miles on One Tube"

That's rather a strong statement, but The Radio Parlor, 2671 Broadway, New York City, say that they have the actual proof that their new one-tube set does it. They are merchandising the circuit with a complete list of parts and a simple diagram for the hook-up.

WGY Will Celebrate The Centenary of "Home Sweet Home"

THE centennial of "Home Sweet Home" will be observed by WGY, the Schenectady broadcasting station of the General Electric Company, Tuesday evening, May 8. It is particularly appropriate that WGY should observe the hundredth anniversary of this song because its writer, John Howard Payne, lived for three years in Schenectady as a student at Union College.

He entered Union at the age of thirteen years in 1809 and that year, while homesick and penniless, he wrote a poem which he called "Home Dear Home." The manuscript of this poem is now treasured in the archives of the college. During his third year at Union Payne was obliged to leave college to relieve the financial burdens of his father and at the age of sixteen began a stage career which gave great promise.

Eleven years after he left Union and seventeen years after he had written his poem "Home Dear Home," Payne wrote a second poem on the same theme and called it "Home Sweet Home." This poem was included in a batch of play manuscripts which he sold a London producer for £250. On May 8, 1823 "Home Sweet Home" was sung during the opera "Clari, or Maid of Milan." The opera was a failure, it is unknown today, but the song achieved almost instantaneous popularity. Its popularity was not that of the songs of today for it touched intimately the lives and experience of people of all times and places. Today, one hundred years later, "Home Sweet Home" has lost none of its appeal and that one spark from the genius that was Payne's still glows.

After twenty years' absence from the United States Payne returned and for several years engaged in literary work. In 1842 he was appointed consul at Tunis, was recalled in 1845 and reappointed in 1851. Two years later on April 9 he died in Tunis. Thirty years later the body was brought to America and reinterred in Oak Hill Cemetery, Washington, D. C., with the highest honors.

Dr. Charles Alexander Richmond, president of Union College, will give an address from WGY, May 8, telling the radio audience about the boyhood of Payne. The Union College Glee Club will sing "Home Sweet Home." W. T. Hanson, Jr., author of a book on the early life of Payne and possessor of a large collection of Payne letters and manuscripts, will also deliver an address.

Broadcasted!

IN no less a journal than the London *Spectator* appears the verb "broadcasted." There is no more reason for using "broadcasted" than there is for saying "casted" and "forecasted," contends the Providence, R. I., *Journal*. Long before radio came into existence the verb "to broadcast" was in good and regular standing. Its meaning, of course, was, and still is, "to disseminate widely." We do not say: "He casted a stone at me," or "The weather bureau forecasted a storm yesterday." And there is no justification for tacking on a superfluous "ed" in the case of broadcast.

Something Radio Cannot Raech

Scientists can magnify the human voice 12,000 times, according to the Brockville, Ont., Recorder, but they seem unable to do a darned thing for the voice of conscience.

Ready For You

Now you can sit on summer like a Polar Bear on a cake of ice—No Troubles at all!!

When our investigators first spoke of it we were surprised ourselves, but now we have the actual instruments in stock and ready to ship to the real radio fans who are determined to eliminate summer troubles. You can sit on the verandah this summer and with the NAVY TYPE D TRANSFORMER in your hook-up, hear the best the U. S. A. has in entertainment.

We have enough NAVY TYPE D TRANSFORMERS on hand to fill the first 300 orders. Send at once for yours.

Radio Bugs and the Radio "Buggy"

By C. W. TUCKER

HEY, look at the crazy guys!" shouted a boy to his playmates across the street as an automobile containing three serious-looking men wearing radio head phones passed through Greenwich Village in New York City. "They got a radio in that car!" But they weren't crazy; not even mildly insane. They were three New York radio engineers—Col. N. H. Slaughter, L. M. Clement and A. S. Santos—returning from an all-night vigil at the radio station at Deal Beach, New Jersey, where they had been "listening-in" on SPE, the International Western Electric Company's radio-broadcasting station at Rio de Janeiro, Brazil, 5,000 miles away. But that isn't the burden of this story. Five thousand miles is not a record for SPE, which has been heard 8,000 miles away, at Honolulu.

Shortly after leaving Deal Beach Mr. Clement, who occupied the rear seat, holding on his lap the seven-tube "baby" which did such good work the night before, became restless, put on a headset and started twisting the knobs and swinging the loop antenna. Soon the strains of an organ floated in on his sensibility, which he knew could be nowhere else but at John Wanamaker's, Philadelphia.

"I got WOO! I got WOO!" What the driver, Col. Slaughter, got was "Whoa! Whoa!" And he brought the car up with a jerk. The other members of the party, when they learned what was going on behind their backs, donned head phones and started merrily on their way.

Rounding a turn in the road Handel's "Largo" on the pipe organ was replaced by "Runnin' Wild," being played by a remarkable jazz organization at WAAM, Newark. This, of course, was caused by a different pointing of the loop. Just then a big truck lumbered by, and the "bing, bang, bang, bing, bang, bang" of the ignition system registered in the ears of the listeners. Every spark was a bang that obliterated broadcasting for the moment.

About two miles ahead, at the top of a hill, could be seen the garage at which it was expected to replenish the gas tank. Just at this time the operator swung the loop around, and WJZ at Newark said: "After the reaction in yesterday's market oils opened strong this morning. South American oils advanced slightly, and Standard advanced a half point." The chauffeur bent over his wheel and stepped on the gas. He must make yonder hill before the price of oil rose. Just then the engine began to miss and sputter. Then she suddenly ceased her circumlocution with a mighty cough. Soundings of the gas tank showed that the slant of the hill was keeping "Maud" from getting the fluid which gave her the kick. Undaunted he turned the car around, backed up the hill, and saved the day.

In Red Bank, New Jersey, a woman stopped spellbound in the middle of the street on seeing the autoists wearing radio ear-muffs. The brakes were applied sharply and the horn gave voice to angry protests against the blockade before she decided to let the "radio buggy" go by. The traffic cop on the next corner paused in wonderment, and said something under his breath before giving the signal to go ahead.

On entering Newark WJZ was transmitting the time signals, and as the radio conveyance passed the Newark market the market quotations were coming in. Apples at four simoleons a barrel; potatoes at 14 kopeks the bag; Bermuda onions at 4,000,000,000 rubles per crate. But time would not permit these radio fans to check up with the retail prices. But here is a hunch for the hurried housewife.

While crossing the meadows the barrenness of the expanse was relieved by the beautiful figures of speech used by Dr. S. Parkes Cadman in his noonday sermon from WEAF. Just as he finished the discourse and uttered the words "Let us pray" a cop rode up alongside of the speeding car, and for the moment the speeders joined in silent supplication. But he passed on, and the trio sighed in relief.

In driving onto the 23d Street ferry boat the once eloquent receiving set was sealed in silence on account of the shielding of the steel frame of the boat. But, by pointing the loop antenna at a steel upright instead of toward the station, the radio travelers were comforted as the vessel embarked on its voyage by "Eternal Father, strong to save, whose arm hath bound the restless wave."

Major Mott's Interesting Station on Catalina Island

EDITOR, RADIO WORLD:

Your request of recent date—for a photograph of my Station — has been received —friend.

* * * *

Herewith one that has just been taken, and I append a short description of apparata on the tables. This I would BEG of you to use, as — each time that a foto of the Station has appeared in the various publications—*without* a description —I have been pestered to death by operators from ALL over the country — asking for DESCRIPTIONS!!

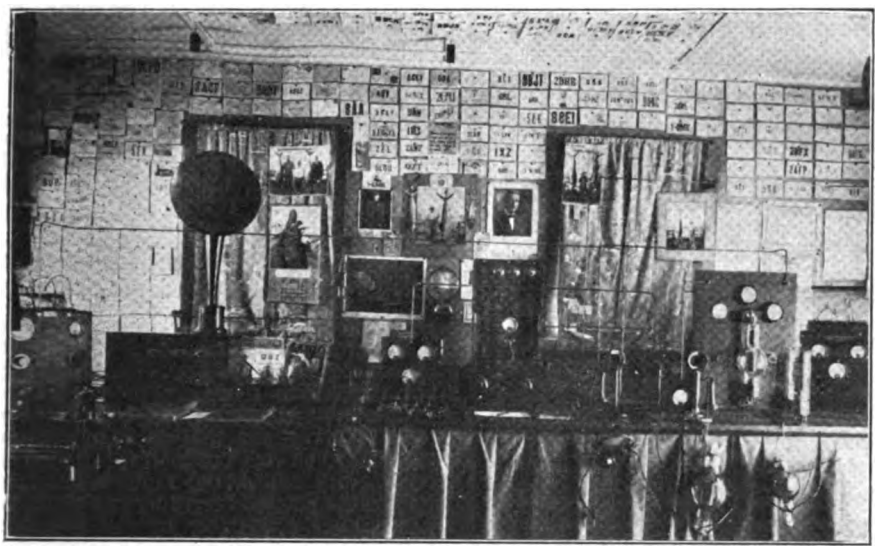
You can save me all this bother by publishing that which I send!

I————THANK————YOU!

Cordially—

LAWRENCE MOTT,
Major—Signal Corps—
O.R.C.—U.S.A.

Avalon,
Catalina Island, Cal.



Station 6XAD-6ZW, Owned and Operated by Major Lawrence Mott, Avalon, Santa Catalina Island, Cal.

DESCRIPTION OF 6XAD-6ZW.
(Owned and Operated by Major Lawrence Mott, Signal Corps, O.R.C., U. S. A.; U. S. Deputy Game Warden.)

Apparatus, from right to left:

1. Combination telephone and telegraph set, using four 50-watt tubes. Power derived from special design m-g set, giving up to 3,000 volts.

2. The big transmitter. So built as to use either a WE-250 (shown at right of panel), a GE-250 (shown in circuit), or either of the two British tubes (Mullard), shown hanging below; one a 500-watt and the other a 250.

3. Special design transfer switch that, by one motion, throws over antenna, counterpoise, ground and power from one to another of the four transmitters, as desired.

4. Antenna switch.

5. Grebe CR-5, with WE design, 2-step amplifier above, and above that a WE-7A amplifier, giving, in tandem, a *wonderful* result.

6. 100-watt transmitter, using two WE-50's on 220 meters, rad. 6.1. On this set, during season '22-'23, I have been reported from Australia, New Zealand, Europe, off the coast of Brazil, in northern Alaska, and from many parts of both the Pacific and Atlantic Oceans. This transmitter has *effectively worked* every district, been heard in every state, and in every Canadian province.

7. Another WE-7A amplifier (in front of magazines). Used in conjunction with new type Grebe CR-7, shown next, with WE Grebe I hear all the larger power stations of the world. POZ is so loud that signals may be read 200 feet from horn.

8. Transmitter, using four 5-watt WE tubes, or one 50 watt. Used for work up to 1,000 miles, though effectively used in '21-'22 in working 3ALN, 3FS, 8BUM, 8AWP, etc.

Twenty-six tubes are used in the sets—chiefly WE. Nearly 1,000 cards and a vast number of telegrams, cables and letters have been received in the passed season. All four walls of the operating room are entirely covered with cards. Only a few shown in the photograph. The ceiling is partly covered.

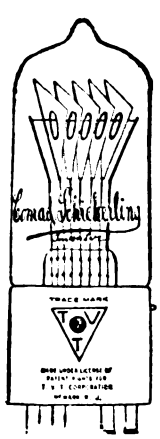
T. V. T. Detector Tubes

BELOW MARKET PRICES



We have just made an exceptionally fortunate purchase of T. V. T. Detector Tubes at much less than regular prices and we offer the public an opportunity to participate in an advantage, which seldom occurs.

The new Triangle Plate Tube is a new invention, making unnecessary the use of grid. It has been thoroughly tested by many of the foremost radio experts and claimed to be far superior to the fragile grid tube in strength, durability and results.

It completely eliminates all the rasping, howling grid noises and distortion caused by the vibration of the grid in all grid tubes.

T. V. T. Tubes are gridless. They are better tubes, scientifically made to reproduce the sound of voice or music free of distortion and harshness, in clear; soft, natural tones.

Every tube thoroughly tested before leaving our firm

Radio Forces Cable Rate Reduction

ANNOUNCEMENT was made last week by the French Telegraph Cable Company, New York City, of substantial reductions in cable rates, effective at once to various countries of Europe. An official of the company explained that the reductions were made because of the increasing competition offered by the radio field.

Both the Western Union and the Commercial Cable Company previously had made announcement of the lowering of their rates, and it was explained that the action by the French company was merely to equalize theirs with the others.

Under the new schedule the rate to Great Britain of all three companies is 20 cents instead of 25; France, 22 instead of 25; Switzerland, 27 instead of 30, and Italy, 26 instead of 31.

Survey of Vacuum Tube Supply Is in Progress

ANNOUNCEMENT was made last week that the National Radio Chamber of Commerce, 165 Broadway, New York City, has undertaken a national survey of the vacuum tube supply in the United States.

This survey, the first to be made, and reported to be well under way, "vitally concerns every one in the radio industry, as well as the public," according to a statement issued after a meeting of the Board of Governors, at which numerous groups were represented. The governors, it was stated, acted at the request of the chamber's membership and of other elements in the radio industry.

Specifically, the supply of the following tubes is concerned: 200, 300, 201, 301, 201-A, 301-A, DV-6, DV-6A, WD-11 and WD-12.

This movement, it is asserted, is part of a program to aid in the orderly development of the radio industry in the interest of both the industry and the general public. Co-operation with the Department of Commerce and other government departments, as well as with universities and public and private institutions, is embraced in the plans.

Nova Scotia Radio Station Wanted

APPLICATION to the Canadian Department of Marine, Ottawa, has been made by C. F. Crandall, president of British United Press, on behalf of American Publishers' Committee on Cable and Radio Communications, for a license to erect and operate a wireless station on St. Margaret's Bay, Nova Scotia. For nearly a year an experimental station of moderate power has been operated at Halifax. This service has proved so successful that a larger station is desired.

"Loops is Loops"

MANY radio fans, when a loop is mentioned, always visualize a set operating with six or seven tubes, a loud speaker, and in general about three or four hundred dollars worth of apparatus. That is, of course, if they make their own sets. They do not realize that there are numerous advantages to a loop that can not be obtained by the use of an outside antenna. Of course, it is to be understood that for really long distance work you have to use an outside antenna, unless you incorporate three or four tubes, with radio-frequency, etc. But if you are content with quiet reception, over a medium distance, with freedom from disturbances such as interference and numerous other things, no better antenna could be used than a loop.

It is not necessary even to incorporate multi-tube reflex circuits, but if the apparatus is handy, a one or two-tube reflex, using a crystal detector will work surprisingly well, and will give you the advantage of wonderful selectivity.

Apart from that, the one other big advantage lies in the fact that you will not be bothered so much in your tuning with the tuning proclivities of your neighbors which sometimes amount to bedlam when they all get going at once, trying to get in PWX, while their neighbors are trying to hunt for KFI, and a hundred others.

Try it out on a loop and let the other fellow howl when he is bothered by interfering stations.

Finds RADIO WORLD Newsy, Interesting and Helpful

EDITOR RADIO WORLD: I am a "newsstand subscriber" to your paper and find it very helpful and interesting.

I think RADIO WORLD is about the best of its kind because it comes out every week and has all the latest "dope" on radio.

Yours truly,
FRED GOLDIN.

Bryant Hotel,
San Francisco, Cal.

Who Did This?

EDITOR, RADIO WORLD: I would like to ask, through your columns, if any fan heard a broadcasting at 4:30 to 5 a. m., April 23, as follows: A Duet from "Il Trovatore," Soprano and Tenor; Military Band playing "Stars and Stripes Forever" and "The American Patrol."

Call letters were not given, and seemed to be at a great distance. Who was it?

Woodhaven, N. Y. CONSTANT READER.

NOW IN PREPARATION

Radio World's Special Vacation Number

Advertisers who want to reach proprietors of summer hotels, summer camps, etc., and owners who contemplate equipping their country homes, yachts, motor boats and automobiles with radio sets can reach them quickly and effectively by using space in RADIO WORLD'S SPECIAL VACATION NUMBER.

Our Circulation Department is making special efforts to reach all these potential buyers of your goods, and to see that a copy of THE VACATION NUMBER is placed in their hands so that they cannot fail to read the advertising announcements as well as our text pages.

RADIO WORLD'S VACATION NUMBER will be unusually interesting, be profusely illustrated with outdoor radio pictures, full of the snap and go of outdoor life, and its many special articles and illustrations are designed to make readers want the goods offered by our advertisers.

REGULAR RATES WILL BE IN FORCE AS FOLLOWS:

One page: One time—$150.00.
Half, Quarter, Third and Two-thirds pages at proportionate rates.
One inch, one time—$5.00. Per agate line—$0.40.
On four consecutive issues—10% discount.
On thirteen consecutive issues—15% discount.
Cover and preferred-position rates made known on application.

Terms: 30 days net. 2% 10 days.

CLASSIFIED ADVERTISEMENTS

Five cents per word. Minimum, 10 words. Discount of 10% on 4 consecutive issues—15% on thirteen consecutive issues. Cash with order.

ELEMENTS OF RADIO TELEPHONY, by Wm. C. Ballard, Jr. A standard book on radio telephony, the work of a recognized authority. Accurate, simple, clear, reliable and strictly up-to-date. For the technical man who wants to post himself on radio and for the radio enthusiast who wants the fundamental principles of radio and their application tersely and entertainingly presented. Price, postpaid, $1.50. The Columbia Print, 1493 Broadway, New York.

RADIO FANS AND PROFESSIONALS—How many of you know the correct CODIFICATION of all characters, punctuations and signs (such as $, %, etc.). We dare say that nine out of ten don't know them correctly! Our instructor who has had 35 years experience, eight years of which were with Uncle Sam as MORSE and RADIO TELEGRAPHER, has just published the first and only CHART known to give fully a true and correct CODIFICATION of ALL characters used in both codes. This CHART is indispensable to all up-to-date beginners and veterans alike. Fifty cents (money order preferred) will bring CHART, also much information extremely interesting to BOYS and GIRLS; because, with this information and a little PEP on your part, you can qualify shortly (as scores of our graduates have done) and secure positions paying $1,500 to $3,000 yearly. (See Civil Service Bulletins 215, 357 and 54.) We are registered with the U. S. C. S. Com. at Washington and can help you. AMERICAN TELEGRAPHIC STUDIO, BOX 793, WORCESTER, MASS.

BECOME A MILLIONAIRE over night! I'll send you one million Russian roubles for $2.00. 500,000 for $1.50; 100,000 for 50c. American Sales Co., Box 1278, San Francisco.

EXCHANGE LETTERS with friends everywhere. Pleasant pastime. Information for stamp. Smith, Box 3125, M. Portland, Ore.

RAND-McNALLY RADIO MAP OF UNITED STATES—Is 28 x 30 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover. Price, 35c. The Columbia Print, 1493 Broadway, New York City.

THE ANNIVERSARY NUMBER of Radio World was increased in size and is an exceptional issue. A few copies left at 15c. each, or you may start your subscription with that number. RADIO WORLD, 1493 Broadway, New York.

ELEMENTS OF RADIO TELEPHONY

By WILLIAM C. BALLARD, JR.

Assistant Professor of Electrical Engineering, Cornell University

This is a standard book on radio telephony, the work of a recognized authority.

It is accurate, simple, clear, reliable and strictly up to date.

The man with a technical background who wants to post himself on radio will find this exactly the book for his purpose.

The radio enthusiast will find in it an excellent presentation of fundamental principles and their application.

SENT POSTPAID ON RECEIPT OF PRICE, $1.50, BY

THE COLUMBIA PRINT, 1493 B'way, New York City

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

Fully Illustrated. Price 75 Cents

IN addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

If You Have a Piano, a Bed Spring or a Picture Moulding, You Have an Antenna!

THERE are many landlords and owners in the cities who, even in these days of enlightenment and science, refuse to allow tenants to string antennas on the roof, and for that reason many would-be radio enthusiasts lose interest. This, of course, is not always the case where a person can get a loop set, but supposing one can't? What are you going to do? Well, there are several ways out of this particular difficulty which serve just as well for local work, and even do some DX work when the set is functioning well.

Ever try using the piano for an antenna? It works quite well in the following manner, and doesn't bother little sister's music lessons: Attach a wire to the iron frame upon which the strings are held. Then go ahead.

Another good idea is to string a wire around the picture moulding in two rooms, using the open end as a regular antenna.

Or attach a wire to the bed-spring. Don't laugh and show your ignorance! WIP has been picked up on a single circuit receiver using one tube, with a bed-spring antenna.

Or if the above are not odd enough for you, try this one: Coil an insulated wire tightly around a tube (No. 16 or 18 wire is about right) and let it stand tightly coiled for a couple of days. Then gently loosen it up, and leave it coiled hanging loosely near your set and use one end of it for an antenna. Or better yet, put it out your window and let it hang for about eight or ten

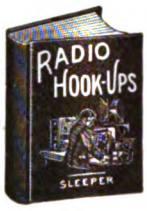
IF YOU ARE INTERESTED IN RADIO YOU NEED THESE BOOKS

RADIO BOOKS THAT HELP YOU

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Radio Hook-Ups

By M. B. SLEEPER

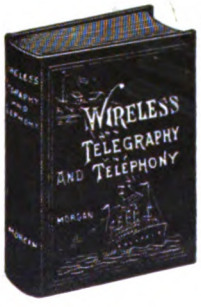
A book that gives you not only clear diagrams for all kinds of telephone and telegraph receiving and transmitting sets, but simple descriptions of each circuit shown and spaces for notes of results obtained.

PRICE 75c.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

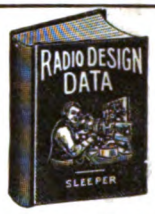
There is a peculiar fascination about receiving radio messages from the high-power stations of England, France, Germany, Russia and Italy, as well as those located in the Pacific Ocean and the Oriental countries. Several types of simple receiving sets for this purpose are described, with detectors and amplifiers to accompany them. Suggestions are also given for operating relays and reproducing the signals on a phonograph. Schedules of operating time for high-powered stations are given. In addition, there is some valuable data on home-made wavemeters for testing and experimenting .....PRICE 75c.



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50



Design Data for Radio Transmitters and Receivers

By M. B. SLEEPER

The only book that gives tables and data for designing, receiving and transmitting apparatus so that you need no knowledge of mathematics. It's the first book a beginner buys after he has learned the use of his phone receiver.....PRICE 75c.

Construction of Radiophone and Telegraph Receivers for Beginners

By M. B. SLEEPER

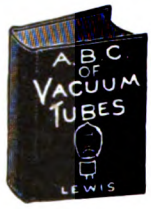
The man who wants to feel the real thrill of accomplishment, and who is not satisfied in the merely making use of what others have done for him, builds his own radio apparatus. Radio men can follow the data in "Radio Phone and Telegraph Receivers" with full confidence, because each piece of apparatus described was first made, tested and found efficient before the final design was accepted. Special receivers, both crystal and audion, are shown in detail. Regenerative circuits as well as audio and radio frequency amplifiers are described with clear photos, diagrams, and working drawings prepared especially for the novice and the man who wants to receive the radio telephone broadcast. A special feature is the phonograph type radio set and the loud speaker. Fully illustrated.....PRICE 75c.

The Radio Experimenter's Handbook

By M. B. SLEEPER

Throughout the preparation of this book, one purpose was kept in mind—Answer the Practical Questions of the "Novice," of the "Beginner," and the more advanced "Student." This book will help in the selection or construction of simple apparatus for the transmission and reception of radio telegraph and telephone signals. In the chapters on radio receivers the simplest crystal, the simple audion, and the regenerative types are described in quite some detail. The question of antennas, both for transmitting and receiving, are taken up. A good many helpful suggestions are given which will be of considerable aid to the experimenter. 16 chapters. Fully illustrated.

PRICE $1.00



The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

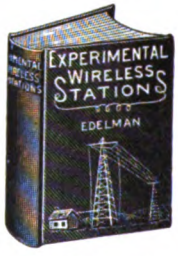
Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

How to Make Commercial Type Radio Apparatus

By M. B. SLEEPER

This book describes in detail many commercial types of spark and vacuum tube telephone transmitting and telegraph and phone receiving equipment of all kinds. The experimenter will be able to get a world of ideas for the design and construction of his next piece of radio equipment from the very clear descriptions and the 98 clearly illustrated figures.....PRICE 75c.



Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations.....PRICE $3.00

How to Construct and Tune a One Bulb Regenerative Set for Long Distance Work

By C. H. Stoup

THE writer, in this article, describes a one-bulb outfit from aerial to ground, on which we hear regularly broadcasting from Havana, Cuba; Denver, Col.; Canadian and California stations from a location near Pittsburgh, Pa. Any set may occasionally hear a long distant station but for regular long distance work this outfit, when correctly assembled, cannot be beaten for efficiency as a one-bulb set.

First, make sure that every part or instrument you purchase is of the very best. It takes high grade parts to get satisfactory results from a radio set. Buy only known apparatus at a reliable electric store which handles a complete line of radio supplies.

Be sure everything is wired correctly by making one connection at a time, then checking with the diagram to see if the connection is exactly right. The accompanying diagram has been checked and rechecked to make sure it is O.K., so follow it in every detail.

Make all the leads as short as possible, particularly the connection between the grid leak condenser and the grid. Solder wherever necessary. Don't run the connection wires of your set parallel. Insulate everything perfectly.

(*Continued on page* 8)

Artificial Lightning and Thunder Startle Electrical Engineers

FOUR hundred electrical engineers who attended the spring meeting of the American Institute of Electrical Engineers at Pittsburgh last week were startled while visiting the Westinghouse new high-voltage testing laboratory at Trafford when one million volts were shot into two brass spheres placed several feet apart. The unexpected display and its resulting blinding flash, similar to a streak of lightning out of a clear sky, and the crashing, man-made thunder, which could be heard a mile away, nearly knocked several of the engineers off their feet.

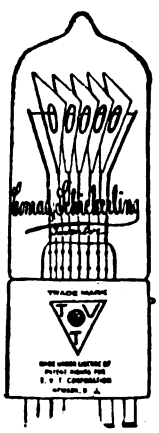
A wonderful illuminating effect was next produced by drawing a high-voltage arc over a distance of 25 feet. This demonstration, which lasted for three minutes, lighted up the entire laboratory.

The electrical engineers inspected every phase of the new laboratory and its facilities for testing power apparatus, insulators and line material that will be used on high-voltage hydro-electric transmission lines and also for the fast developing super-power systems that are being contemplated throughout the country.

The laboratory is equipped with 1,000,000 and 500,000 volt testing transformers and apparatus

T. V. T. Detector Tubes

BELOW MARKET PRICES



We have just made an exceptionally fortunate purchase of T. V. T. Detector Tubes at much less than regular prices and we offer the public an opportunity to participate in an advantage, which seldom occurs.

The new Triangle Plate Tube is a new invention, making unnecessary the use of grid. It has been thoroughly tested by many of the foremost radio experts and claimed to be far superior to the fragile grid tube in strength, durability and results.

It completely eliminates all the rasping, howling grid noises and distortion caused by the vibration of the grid in all grid tubes.

T. V. T. Tubes are gridless. They are better tubes, scientifically made to reproduce the sound of voice or music free of distortion and harshness, in clear, soft, natural tones.

Every tube thoroughly tested before leaving our firm

ELEMENTS OF RADIO TELEPHONY

By WILLIAM C. BALLARD, JR.

Assistant Professor of Electrical Engineering, Cornell University

This is a standard book on radio telephony, the work of a recognized authority.

It is accurate, simple, clear, reliable and strictly up to date.

The man with a technical background who wants to post himself on radio will find this exactly the book for his purpose.

The radio enthusiast will find in it an excellent presentation of fundamental principles and their application.

A Home-Made Radiophone Set of Great Range

By Dr. B. S. Bickelhaupt

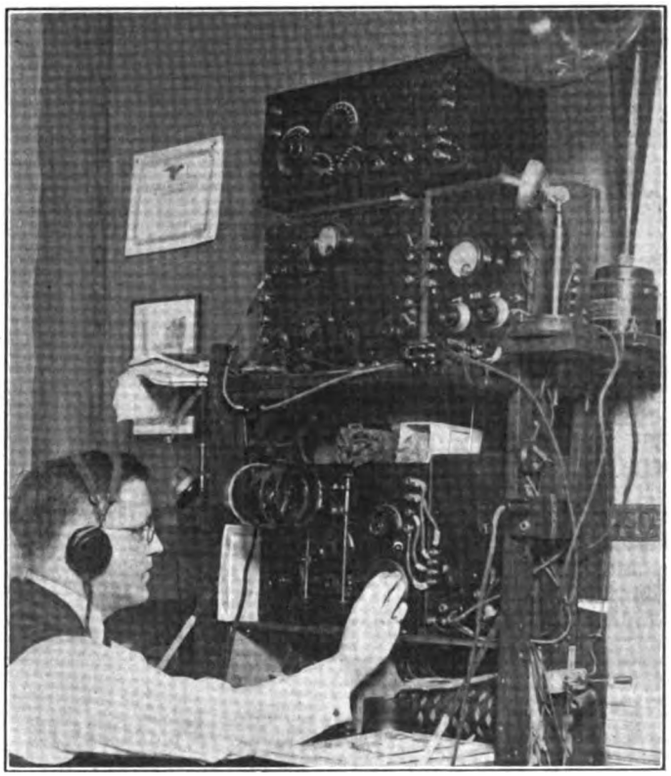
A NEAT and efficient amateur radiophone station is that with the call 2CBA built, owned and operated by Dr. B. S. Bickelhaupt, 376 East 162nd street, New York City. The entire apparatus for both the receiver and transmitter was constructed by the owner, who describes it as follows:

"The receiver shown is not the type that the reader usually runs across, in that it is not of the regular honeycomb type. It is a single layer coil set employing regenerative principles with both inductive and capacity feedback. The method is known to produce the best results. I have been using this for the past two years and have come to regard it as the most reliable outfit any one can handle. Any station broadcasting that is powerful enough to reach me will be heard and the statement is made with that reservation since freak reception of a weak station occurring once in a blue moon should not be accepted as representing the consistent range of a station. I have heard practically all stations within a 1,200 mile radius. Amateurs have been heard from practically every state.

"The transmitter is a tube set employing four 5-watt tubes. With a fairly low plate voltage (350) I have consistently covered a radius of 200 miles even in summer with all the attendant drawbacks. During the winter, of course, the range is materially increased, my station having been heard in Michigan and Missouri which means also the intervening territory as well. The set is tuned to 200 meters but provision has been made to reduce to 178 meters for testing purposes. Occasionally as low as 150 meters has been used, although I have as yet been unable to determine the efficiency of the set at this point.

"The entire outfit has been self-constructed and since I have first made it there have been many changes, with subsequent improvement in the outfit to bring it up to its present standard of efficiency. There is only one contemplated change, and that is the addition of two steps of radio-frequency which may be switched on at will.

"I shall be pleased to advise anyone on the constructional details of any part of my equipment, should they care to write me."



(C. Photonews, N. Y.)
Dr. B. S. Bickelhauft, of New York City, and his long range station 2CBA.

Radio Transmission Records by Cruiser "Omaha"

NAVAL radio experts are delighted with the performance of the radio equipment on the new scout cruiser "Omaha," which recently broke all long distance records in transmitting during her "shakedown" cruise in the Pacific.

While maneuvering at sea off the coast of Washington, the newly installed radio transmitting sets were given a thorough test. Code messages transmitted with the 20 KW arc set such as the larger naval craft are now equipped with, were copied by all naval radio stations along the west coast from lower California to Saint Paul, Alaska, and on the east coast at Bar Harbor Me., Washington D. C., and Key West, Fla. One of the stations reached was San Diego, 1,800 miles away from the "Omaha." This new cruiser's arc was copied by the battleship "California," which was 1,800 miles distant, but it is reported that the "Omaha" could not pick up the "California's" replies.

Not only in code dispatches did the "Omaha" radio experts excel, but with her 300-watt tube set, spoken messages were transmitted to Pearl Harbor, Honolulu, 2,300 nautical miles distant. They were also heard at Key West, Fla., approximately 2,100 miles over land and sea.

Part of the credit for the long-distant work is attributed to the 180-foot wooden masts, which carry the "Omaha's aerials almost 50 feet higher than the steel masts on battleships. The mean effective height on the "Omaha" is better than 100 feet, it is stated by naval experts. Her radio equipment is also installed on the "top-side."

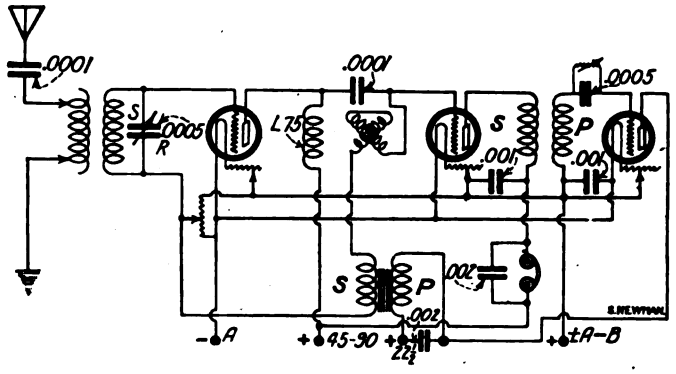
A Flexible and Selective 3-Tube Reflex Circuit

By H. Parsons

HAVING been experimenting during the past few months with the popular reflex type of receiver I finally hit on one that I think is about the best of them all. It is a modification of several and is very selective.

As every one knows, the main trouble with the reflex type of receivers is their lack of selectivity or "sharp tuning." If this set is carefully constructed and the best parts used the builder will be pleasantly surprised at the remarkable selectivity he can obtain if it is handled carefully and the tuning done systematically instead of just "turning knobs and dials."



Flexible yet very selective reflex circuit designed by Mr. Parsons. All the capacities and constants are specified in the drawing.

The tuner of this circuit consists of a Dayton moulded bank-wound variocoupler with secondary shunted with a 23 plate vernier condenser. It is imperative that the best apparatus be used.

The variometer which is used as a radio-frequency tuner is of the same make with all the condensers the popular micadon with brass cover. I specify this because of the liability of the paper condensers to blow if anything happens. If this should occur the circuit would be rendered inoperative and you would have to test each one, so a little extra expense will save a lot of trouble. The rheostats are all vernier control, six ohms resistance. These will handle the current for all the now popular types of tubes.

The radio-frequency transformer is an Acme R-2 and the audio-frequency is a Federal 226-W. It is not absolutely necessary to use these types or makes if another of high quality is on hand, but be sure that it is of the same ratio as those specified. The honeycomb coil can be of any popular type, either the D-L or the regular wound. If it is desired, a non-inductive resistance can be used in place of the honeycomb coil, and the B battery increased. This will then give resistance—coupling—amplification on the first tube.

When hooking up it is absolutely necessary to see that the leads are all as short and straight as possible. It is better to incorporate "B" line leads using lighting cable (one strand of the twisted kind) than it is to use bare bus wire. Run your leads direct and prevent them from bunching and crossing at anything but right angles, or capacity coupling will result and the selectivity will be nil. Group your A and B leads to give as much inductance effect as possible and at the same time keep down the capacity.

When tuning in first set your primary at the approximate point of resonance and tune your secondary condenser. Then using the variometer bring in the signals until the volume is at its highest point and the noise is cleared up. Now tuning with the potentiometer bring the signals in as loud as possible with the least amount of scratching. If the potentiometer is turned too far the circuit may howl and scream. It is important that the grid leak is set at the right point for the detector you are using. At this stage it would be best to get a panel mounting condenser and leak combined, as then the resistance can be changed with the least amount of trouble. It is ofttimes necessary to tune with this leak when real distance work is being done and there is a great amount of local interference.

Long Distance Radio Tests on Pacific Planned

RECENT tests between the Shipping Board Steamer "Easterner" and some land radio stations showed reception from East Hampton, N. Y., at 6,000 miles, while several other stations were heard almost continually throughout a cruise from Panama to Australia. These results were so surprising that further tests between high-powered Naval stations and Shipping Board vessels in the Southern Pacific are planned.

This interesting report received via the Shipping Board from the radio operator of the S.S. "Easterner," which recently made a cruise to Eastern Australia via the Panama Canal follows in part:

"Conditions in the South Pacific appear to be ideal for radio work. On both passages, I was favored with negligible static and interference in mid-ocean except about the equator. Using one step of audio-frequency amplication, the following results were obtained:

Atlantic Stations—	Call	Miles
East Hampton, N. Y.	WSA	6000
Cape May, N. J.	WCY	5200
Point Isabel	NAY	4000
Morehead City, N. C.	NAN	3100
Key West, Fla.	NAR	3000
Pensacola, Fla.	NAS	3000
Pacific Stations—		
Vancouver	VAE	5200
San Diego	NPL	4200
Honolulu	NPM	3400
New Zealand	VLC	2500

"Arlington was heard at 4200 miles. The high power stations Balboa (NBA), San Francisco (NPG), San Diego (NPL), Honolulu (NPM), and Guam (NPN) were all heard over practically the entire Pacific ocean from Panama to Australia. Longer wave stations could not be heard because the coils loaded only to 11000 meters."

The data from the "Easterner" was considered of such value in connection with the communications in the Pacific ocean, that immediate steps have been taken to arrange tests between high-powered Naval radio stations on the Pacific Coast and Shipping Board vessels making cruises to the South Pacific.

A Portable Loop Set That Works Easily and Well

By Kenneth Malcolm, A. I. R. E.

ONE of the easiest ways to secure great selectivity, and at the same time reduce static disturbances to a minimum, is to use a loop antenna. Loops are generally located indoors and at no great height, where strays or atmospherics are present only in negligible quantities. Due to their marked directional characteristics they allow differentiation between stations of equal power but which lay at varied angles from the receiver. Loop sets also offer the advantage of simplicity and portability.

The greatest drawback that stays the hand of the average fan, is the idea of cost; for he thinks of a

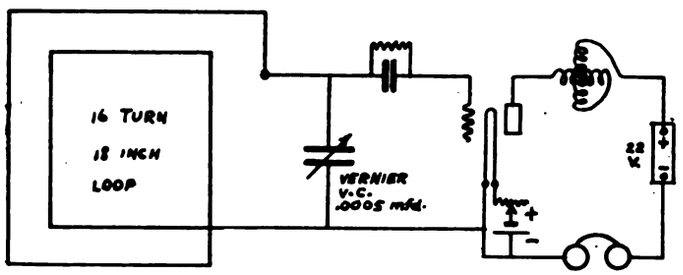

Fig. 1—Hook-up for Mr. Malcolm's Portable Loop Set.

loop set as always necessitating a half dozen or so stages of radio-frequency amplification. This is all well and true for DX work, but for reception over comparatively short distances—under 25 miles—a loop set can be constructed at small cost that uses but a single tube and at the same time employs a standard circuit. It is also the acme in portability and ease of operation.

Apparatus varies somewhat in size, but the dimensions given may act as a guide. The panel should be about 8½ inches wide by 7½ inches high. The cabinet should be about seven inches deep.

Other parts include a .0005 mfd. variable condenser (values depending upon the particular tube used), a variometer, rheostat, tube socket, tube (either dry cell or regular 6 volt), a single circuit jack with plug, three dials or knobs, about 70 feet of wire for the loop, several pieces of wood for the loop frame, A and B batteries, phones, and the necessary binding posts.

Secure the best apparatus that your money can buy and you will be more than repaid by the good results. If you desire, the set can be entirely self-contained by using a dry cell tube and securing a cabinet large enough to include the batteries.

Let us start by constructing the loop itself. Secure some wood about ½ or ⅝-inch square, and cut one piece 25 inches long and another 19 inches long. These may be best fitted together by using the half-lap joint, the joint commonly used on the cheaper Christmas tree standards. The two parts might be glued and a small brass screw or bolt passed through the center to make it strong and rigid. The outside turn of the loop is a square whose diagonal is 18 inches. The turns are spaced ¼-inch apart. There should be 16 in all, and they may be held in place by small brass screws, or small wood dowels that have been glued into holes bored in the cross-pieces. Iron or steel screws are especially undesirable. Most any sort of wire may be used, but Litzendraght has the lowest radio-frequency resistance and is therefore preferable.

The mounting of the loop is unique but simple. Secure a plug with a round insulating sleeve of a diameter sufficient to admit the end of the long loop shaft; you may have to cut off part of the end of the sleeve to do this. Fasten the two leads from the loop to the terminals of the plug and anchor the shaft by means of sealing wax or some other insulating cement. The corresponding jack should be mounted near the rear left hand corner of the top of the cabinet. This combination forms a simple and efficient means of rotating the loop and also allows the loop to be dismounted from the set at a moment's notice, for facility in packing or for the inspection of the set.

Next we can drill the panel and mount the instruments. The arrangement shown in the drawing is highly recommended. The left hand dial controls the variable condenser, the right hand the variometer, and the small dial at the lower center controls the rheostat.

With this type of circuit a condenser having a vernier is absolutely necessary; however, a separate vernier may be used, if you have one. The grid leak and grid condenser may be of a fixed value, and mounted inside the cabinet. Too much stress cannot be laid upon the value of a good grid condenser. Those having a mica dielectric are the most dependable, but there are a few good manufacturers who use paper. If you use a very critical tube it may be an advantage to have a vernier on your rheostat, otherwise this is not very important.

If you want to make your set truly portable, the WD-11, WD-12, and the UV-109 tubes are ideal.

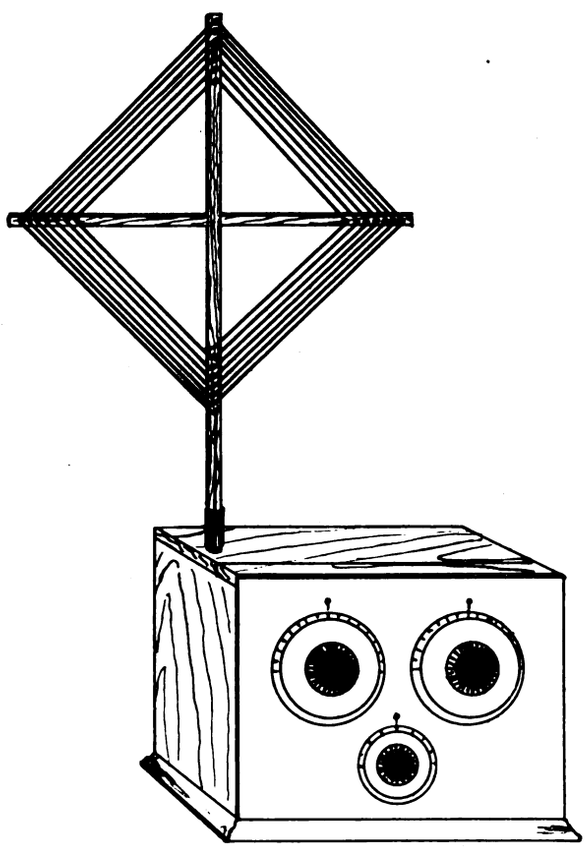

Fig. 2—Assembly of the Portable Loop Set Designed by Mr. Malcolm.

As, by its natural characteristics, a loop can absorb but a small percentage of the energy that could be absorbed by an open or regular aerial, every effort should be made to prevent losses. Whereas with the best of

Radio and the Woman

By Crystal D. Tector

(C. International Newsreel)

Blanche Sweet, charming star of the silver screen, interprets various facial emotions while listening over the radio. Reading from top to bottom, at the left: Bedtime Stories—"The Big Bear Jumped on the Little Rabbit." "Every one keep quiet, sh-sh-sh!" "Ouch! What noises!" At the right, from top to bottom: "Well, that's a good joke!" "Isn't that a good song? It makes me laugh!" "Oh, boy, that's real jazz! Come on and strut your stuff!"

Friend Husband has been real busy of late, coming home late, tired and too worn out to even read the evening papers. The reason is that he recently went into a partnership with a bright young star in legal circles. He told me this morning that he never realized until now what a real comfort radio was to people who were tired. "I never appreciated it before because I took it more as a pleasant game to be played by turning dials, but now when I am tired it is a real pleasure to sit in my comfy chair and listen to all that beautiful music and the news of the day. I just close my eyes and rest, and the world passes in review through our loud speaker:" Well, it certainly took him long enough to appreciate the work of the different broadcasters.

* * *

I have a letter from Mr. H. H. Taylor, advertising manager for the American Radio & Research Corporation, Medford Hillside, Mass., about the picture of Miss Thompson which appeared on the front cover of RADIO WORLD for April 28. Mr. Taylor takes issue with the title used over the picture, "Only Woman Graduate of a Radio School," and states that a year ago there were half a dozen women graduates of radio schools and that this number doubtless has increased since. My correspondent also informs me that Miss Eunice L. Randall, who gives the bedtime stories at WGI, his company's broadcasting station, is a graduate from the Eastern Radio Institute of Boston. Miss Randall is also a licensed operator (1CDP). If Mr. Taylor will read the caption below Miss Thompson's picture he will find her described as "the only woman graduate of the radio school she attended," etc. This is all very interesting and I would thank Mr. Taylor, or any others who read RADIO WORLD, to send me the names of women graduates of radio schools they may know. I have something I want to say to them.

(*Concluded from preceding page*)

instruments, assembled with the greatest care, very satisfactory results can be secured with the instrument described, it must also be remembered that with poor or less efficient instruments that have been thrown together with utter disregard of details, the set might not work at all.

So be careful. Use only the best thoroughly seasoned wood for the cabinet if any of the instruments are mounted on it; it is better that the instruments should not be, however. See to it that there can be no leaks in the loop on account of puncturing the insulation of the wire with a screw head. Make all the wiring as short and as rigid as possible, using No. 14 copper wire, or bus bar; this need not be insulated if you take care to arrange it so that there cannot possibly be a short-circuit. It is absolutely imperative that all joints be soldered. A good tube and a sensitive pair of phones will often change an absolute failure into a marked success.

The jack for the loop plug is connected by flexible leads to the other instruments, so that the cover may be opened without hindrance. No mention has been made of the battery and the phone connections, for individual taste varies much on this question. A very neat job may be engineered by mounting a small strip of some insulating material on brackets, inside the cabinet; on this strip are arranged the necessary binding posts for the A and B batteries, and for the flexible leads to the jack. The battery wires may be led in through small holes drilled near the lower part of the back of the cabinet.

Another method is to cut away a portion of the wood of the lower cabinet back, and mount the strip with the binding posts over this. Still another, but more unsightly, way is to mount the binding posts directly on the front of the panel. The phones may be attached to binding posts on the panel, or a plug and jack arrangement may be used.

The tuning is quite simple. First rotate the loop to a position approximating that of the station from which it is desired to receive, the cross-bar being the pointer. Turn on the filament of your tube to an arbitrary value; then manipulate the variable condenser dial. You may rotate the variometer at the same time. At some point you may hear a whistle; now you must carefully re-adjust the condenser and the variometer, and in a moment you will have your station. This may be brought in louder by moving the loop, regulating the vernier on the condenser, and regulating the filament current. The actual operation is really easier than the description.

If at any time you desire to get a greater range than is afforded by the loop, a variocoupler may be added, thus converting the set into an excellent three circuit regenerative receiver, and a regular aerial and ground may be used. Amplification may be added in the same manner as to any other set.

The Improved Cockaday Four Circuit Receiver

By Russell P. May, R. E.

THOSE who have used regenerative receivers know the critical nature of the adjustments, especially that of the regeneration control. This is characteristic of all regenerative receivers, and extremely so in the ultra-audion. A new receiver, the creation of Lawrence M. Cockaday, the adjustments of which are very simple and the results surprisingly gratifying, is herewith illustrated and described. (See also RADIO WORLD, April 28, 1923.) Before going into details it will be well to briefly review the functioning of the regenerative receiver.

The action of the grid in a vacuum tube is to control the amount of current flowing from the plate of "B" battery to the filament. When a slight impulse is received it is impressed upon the grid. This impulse is of alternating character, and the voltage impressed on the grid rises and falls with it. These variations of grid voltage permit a relatively large current to flow in the plate circuit, the result being a true reproduction of the incoming signals.

In order to increase this amplification tubes were connected in such a manner that the output or plate circuit of one tube supplied the input or grid circuit of the next, increasing the signals at each step. Previously it was not known that even better results could be had with one tube when properly connected. It was only necessary for some one to find out how these connections were to be made. This was accomplished, simply and effectively, by Edwin H. Armstrong.

The incoming signals are extremely weak, and the voltages on the grid are likewise feeble, but the currents flowing in the plate circuit are enormous in comparison.

Armstrong placed a coil in close inductive relation to the secondary coil and provided means of varying their relation to each other. This coil was connected in series with the plate circuit, through which the current from the "B" battery had to pass before reaching the plate. A magnetic field is set up in this coil, which field varies precisely with the grid voltages, and, as the two coils are coupled together, this varying field induces varying voltages in the secondary coil. The result is that feeble incoming signals are reinforced, with a corresponding increase in the plate current.

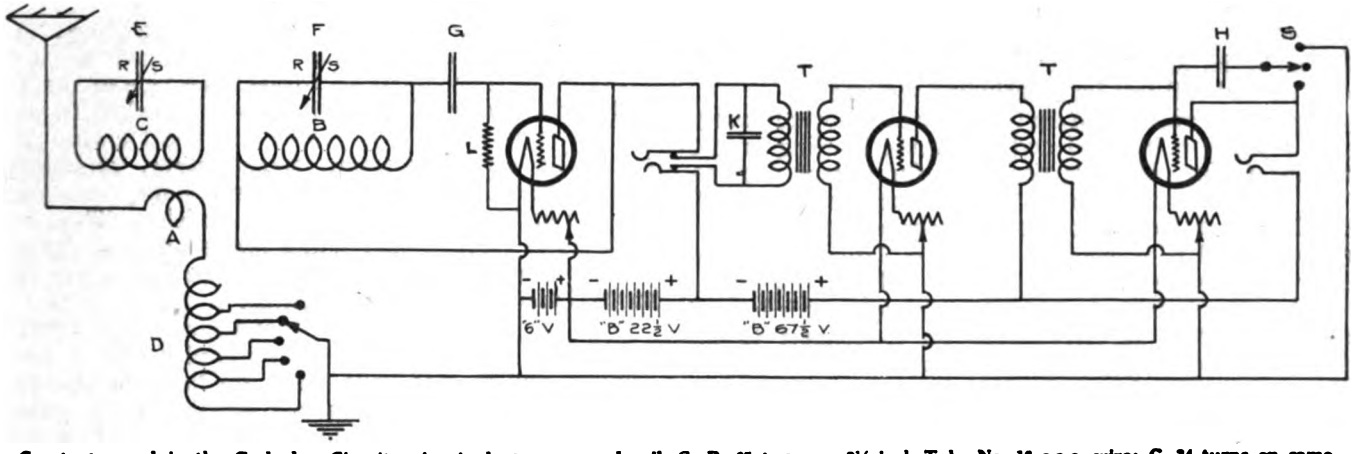
The effect of regeneration in a receiving circuit is to increase the negative resistance of the plate circuit, which is the equivalent of decreasing the effective resistance; so the only limiting factor is the capacity of the tube itself.

Due to this it is necessary to adjust the amount of feed back from the plate to the grid by adjusting the relation of the coils so that the reinforcing energy supplied to the grid could be controlled. There is a point in this action at which the tube will start to generate oscillations itself, and it is at this point that the signals are the loudest.

It is evident that regenerative control depends upon the control of the negative resistance. When it is too great the tube will oscillate, and when too small regeneration becomes weak. At the point approaching oscillation the signals are strongest.

It will be noticed in the diagram herewith that the secondary circuit is not the usual regenerative circuit. It is what is known as the ultra-audion circuit, with the grid and plate of the tube connected to each end of the secondary coil. This type of circuit is extremely critical and oscillates easily. The antenna system is of the semi-aperiodic type, which requires no condenser. It is coupled to the secondary circuit by means of a single turn, as shown at A. Adjacent to the secondary coil the coil C is placed, with a condenser connected in parallel with it. This is what is known as the fourth circuit. Its function is as follows:

When the coil A receives an impulse due to an incoming signal a comparatively high E. M. F. is induced in Coil B as the transformation ratio is very high, and therefore the grid is strongly impressed. On account of this high ratio even the weakest signals manifest themselves in the secondary circuit, and this accounts for the long-distance reception this circuit is capable of. The plate current resulting from this weak signal is therefore correspondingly large. This method, if used in a plain ultra-audion hook-up, would be very unsatisfactory, as any signal would be sufficient to cause it to spill over or to oscillate. It is therefore necessary to provide a means of controlling the regenerative action, and this is accomplished by means of the fourth circuit. The coil C is within the magnetic field of the grid coil B, and when condenser E is varied the reactance between this circuit and the grid circuit is varied. It will be seen that, if the tube circuit is in an oscillating condition, there will be a point in the fourth circuit, or what is known as the stabilizer circuit, at which it will absorb energy from the grid coil B. This is equivalent to inserting resistance in the grid circuit, and, as before mentioned, the grid circuit resistance, positive and negative, determines its point of oscillation. It is evident that if this circuit is in an oscillating condition the stabilizer can be adjusted to absorb enough energy from the grid circuit to just stop it from oscillating where signals will be heard strongest.



Constants used in the Cockaday Circuit: A, single turn around coil C; B, 65 turns on 3¼-inch Tube No. 18 s.s.c. wire; C, 34 turns on same tube 1/16 inch from coil B; D, 43 turns double bank wound tapped at 3, 7, 13, 21, 31 and end (set at right angles to B & C); E and F, .0005 variable vernier condenser; G, .00025 fixed condenser; H, .001 fixed condenser; K, .0005 fixed condenser; I 1 megohm grid leak; T1 Amertran transformer (audio); T2 General Radio transformer (audio); S, 3-point switch.

How to Construct and Tune a One Bulb Regenerative Set for Long Distance Work

(*Continued from page* 1)

Don't expect to get good results on distant stations unless you tune very, very carefully.

A great percentage of the efficiency of your outfit is in the tuning, and if you will learn the purpose of each instrument in your set you will get the most out of it. A combination of a good set with good tuning is what brings you the distant stations.

A single steel copper coated wire makes a very good receiving aerial and should be about 150 feet long, including the lead in; however, 175 or 200 feet will work satisfactorily with this set. The L top aerial, which receives slightly better from the lead in end should be pointed toward the distant stations you wish to receive.

Run your aerial at right angles to power lines, if possible, to avoid inductance. Also keep the aerial at least four feet away from tin roofs, spouting, etc.

Insulate your aerial perfectly with good insulators and solder any splices in case it should be necessary to splice two wires together. A tube insulator such as is used in house-wiring makes a good insulator through which to bring your lead in wire through the window frame or through a board the width of the window sash installed either above the upper sash or below the lower sash.

The higher your aerial the stronger the signal strength; also the stronger the static. However, make your aerial high and you can lower it in summer if you wish. We are using an aerial forty-five feet high at one end, fifty-feet at the other and 150 feet long, including the lead in.

Keep your aerial drawn up tight, for as the wind swings it the capacity is changed and will cause howling on the very fine tuning which is necessary for distant stations.

The material you will need for this set consists of 150 to 200 feet of No. 14 copper or copper-plated solid or stranded aerial wire, enough No. 14 or larger copper or copper-plated wire for your ground. The length of the ground wire will depend on the distance your set is located from where it is necessary for you to connect to the ground and should be as short as possible.

Two antenna insulators, one tube insulator, one standard variocoupler for tuning the primary with the units; ten taps and contact points for each tap; also two switches for the contacts in case you intend to install the set in a cabinet. If you are not going to assemble the set in a cabinet you need not purchase the two switches or contact points, but instead use two small clips, similar to storage battery clips, one soldered to the aerial wire and the other soldered to the ground wire.

In case you have a good variocoupler which is not of the units-tens type you can use it very nicely by the addition of a vernier .0005 variable condenser installed in the aerial or ground circuit. This condenser will allow you to tune your primary or aerial circuit between the taps on the coupler. You will also require:

1 Vernier .0005 condenser for tuning the secondary circuit. (Panel mounting type.)
1 Standard variometer, moulded bakelite preferred, for tuning the plate circuit.
1 Standard detector tube.
1 Standard detector tube socket.
1 Variable grid leak.
1 .00025 fixed grid condenser.
1 Vernier rheostat (for panel mounting).
1 Board.
1 Potentiometer, 200 or 300 ohms for panel mounting type connection across "A" battery.
1 .001 fixed condenser.
1 .002 fixed condenser.
1 Pair good 2,000 ohm phones.
1 22½ volt "B" battery.
1 80 ampere hour storage battery or at least 100 ampere hour capacity if you intend hooking to an amplifier now or at a later date.
15 Feet No. 18 tinned or copper wire for connections.
2 Phone binding posts.
1 Piece of bakelite or hard rubber 3/16 x 6 x 8 inches.
1 Piece of bakelite or hard rubber 3/16 x 1 x 3 inches for mounting phone binding posts.

Follow the directions already outlined for installing the aerial. You should have a pulley on one end so that you will be able to lower the aerial if necessary; also, it will be much easier to keep the aerial tight to prevent swinging. Keep in mind that the aerial receives better from the direction to which your lead in is attached. Your ground wire should be at least No. 14 gauge and should be made as short as possible from your instruments to the nearest water pipe at a point nearest where the water pipe enters the ground. After cleaning the water pipe thoroughly with a file, the ground wire should be wrapped on for about a dozen turns then well soldered to the water pipe. If you do not have a water pipe on which to make a ground connection a gas pipe will do, but as a rule does not make as good a ground connection.

The instruments should be installed on a board one-half inch thick by six inches wide. Everything should be perfectly insulated with all connections made as short as possible, particularly the connection between the grid leak and the grid. All the instruments should be connected as outlined in the diagram and checked over thoroughly to be sure they are right. The plate variometer next to the plate terminal of the vacuum tube, then one side of the phones should be connected to the other side of the variometer, then comes the "B" battery. The rheostat should be connected in the negative side of the filament circuit, etc. The vernier rheostat, potentiometer, variable condenser and .001 fixed condenser are mounted on a piece of bakelite or hard rubber 3/16 x 6 x 8 inches. The variable condenser, rheostat and potentiometer are of the panel mounting type. The bakelite panel should then be attached to the board in an upright position.

The red or colored cord from your phones should be attached to the terminal going to the plus side of the "B" battery, and in case your cords are both the same color you can try attaching them to your phone posts first one way and then the other, leaving them the way in which they bring in the signals loudest. This is important in order to get in the distant stations and give long life to your phones, for if the "B" battery current goes through your phones in the wrong direction it has a tendency to demagnetize the telephone magnets as well as decrease the signal strength.

If you will look over the construction of your units-tens variocoupler you will notice that by proper manipulation of the aerial and ground clips you can cut in one turn of wire at a time from the bottom of the primary to the top with the exception of a few turns in the center of the primary. The primary circuit consists of the aerial, primary, variocoupler and ground connection. The tuning to the wave length you wish to receive is all taken care of by the primary or the variocoupler. The secondary circuit consists of the secondary of the variocoupler, L2; the variable condenser, C1; the grid leak, grid leak condenser and connections. This secondary circuit should be tuned to resonance with the primary. The variometer, L3, in the plate circuit, is for tuning the plate circuit to resonance with the secondary circuit in order to make the set regenerate. The fixed condenser C4 is for the purpose of by-passing the radio frequency currents around the phones and also "B" battery. The radio-frequency current is not required in the phones, as only the pulsating direct current is used to operate the phones; therefore, by shunting this con-

Valuable Advantages of Instruction by Radio in Public Schools

By William L. Ettinger
Superintendent of Schools of New York City

THE experiment in teaching a class by radio, recently carried on at the Haaren High School, New York City, through the courtesy of WJZ and the Radio Corporation of America, was an unqualified success. While I do not believe that this method of instruction will ever do away with the services of the classroom teacher, yet I am convinced that a new field in education has been opened by this experiment, which has wonderful possibilities.

In a large city system it is often necessary to get official notices to schools in a very short space of time. In New York City, where there are over 500 elementary schools, 32 high schools, and numerous special schools, it is obvious that the mere mechanical work involved in sending out such a notice requires the time of a considerable number of people. With a broadcasting station at educational headquarters and receiving sets in all the schools the problem would have a simple and instantaneous solution. All large cities in the country have conditions similar to those in New York City.

Directors of special branches, special teachers and supervisors could give demonstration lessons directly to groups of teachers or classes, with a great saving of the time now wasted because teachers are obliged to travel long distances in order to attend a conference at some central place.

Famous men frequently visit the city, and they are sometimes willing to address school assemblies, but only one or two schools are fortunate enough to hear them. Radio communication would make it possible for all the school assemblies in the city to hear such a speaker if he were stationed at school headquarters. When one considers that schools all over the country may listen in at the same time, the possibilities for hearing great speakers seem to be almost unlimited.

In rural school communities the chances for radio instruction are much greater than in cities. No longer need the rural school be isolated or entirely dependent upon the services of a few poorly trained teachers. The country school-house can now be put in touch with the best instruction in the world by simply installing a radio set.

A suggestion may not be out of place here. Many schools having receiving sets are unable to get much that is worth while during the hours of the day that classes are in session. Could not a movement be inaugurated for having broadcasting stations send out educational programs suited for school instruction during these hours? A movement of this kind would be of great benefit to schools already possessing radio sets and would also be an inspiration to other schools to purchase them.

(*Concluded from preceding page*)

denser around the phones and "B" battery you cut out a considerable amount of resistance for the radio-frequency current which travels through the plate circuit. The fixed condenser, C3, which connects the movable contact on the potentiometer and the plus lead of the storage battery circuit, is used for the same purpose as condenser C4. The ground connection from the plus lead of the storage battery is used to cut out induction.

In tuning for distant stations it is well to first tune in a nearby station on, say, a 400 meter wave length to the exact tune with your primary and secondary circuits, first turning on your rheostat to the point where you hear a hissing in the phones and having the movable contact on the potentiometer set about one-fourth the distance from the plus lead connection of the storage battery and with the vernier plate on the variable condenser about half-way in between the fixed plates of the condenser. This setting of the vernier condenser will allow you to get a fine adjustment by its use after you have already tuned in with the regular condenser dial. You should tap on the 18 volt tap of the "B" battery provided it is reasonably new, otherwise you may tap on for more voltage. The proper tap can be determined by experimenting.

The plate variometer should then be adjusted until the loudest signals are heard in the telephones without distortion. The rheostat should now be turned back and left at the point where you get the signals in loudest with the least amount of noise or hissing and the potentiometer should be changed to the point where you get the signals in loudest without hissing.

Turn on the rheostat a little stronger or until you hear the hissing again and then go after a much more distant station which you know to be on a 400 meter wave length. Change the secondary condenser or the plate variometer or a combination of both, or possibly changing the primary connection one or two turns either way until by careful manipulation you get in the distant station loud, then adjust the vernier rheostat again until the broadcasting is loudest with the least amount of hissing or noise; after which you should stabilize the circuit further by use of the potentiometer. You will notice as you adjust the variometer for a distant station you will first get a squeal, which is the carrier wave, and as you turn the dial slightly the frequency of the carrier wave will become less and less until you reach a point where you cannot hear it and as you turn the dial still further you again hear the carrier wave, the frequency increasing as you turn the dial. The dead or zero point of this squeal is called the "zero beat," and is the best possible adjustment for the reception of music, for then you will have maximum volume and no distortion. You should now change the variable grid leak to the point where you get the loudest signals without distortion, then leave it there, as this is the proper setting for all stations for the detector bulb which you are using. If you should later install another detector bulb you may have to again adjust the grid leak. About one-half megohm is correct for the radiotron or Cunningham detector tubes.

By first tuning in a local or nearby station you get roughly the proper adjustment of your circuits. Then by tuning in a more distant station you get still finer adustment on the circuits for 400 meter wave length. Now if you have tuned in a distant station very carefully you can possibly get a much more distant station or stations by careful adjustment of the plate variometer only. If not successful in this change the secondary tune slightly by use of the variable condenser; then with the variometer, go after the "zero beats" of the carrier waves you may hear.

The three circuit tuner provides the best method of receiving what you want to hear and eliminating what you do not wish to hear. However, you have to pay for the extra distance over which you will be able to receive and for the eliminating of interference, by some very careful tuning. If you do not tune very carefully you can very easily run through some of the very distant stations without hearing them at all.

WEAF, The Last Word in Broadcasting Studios

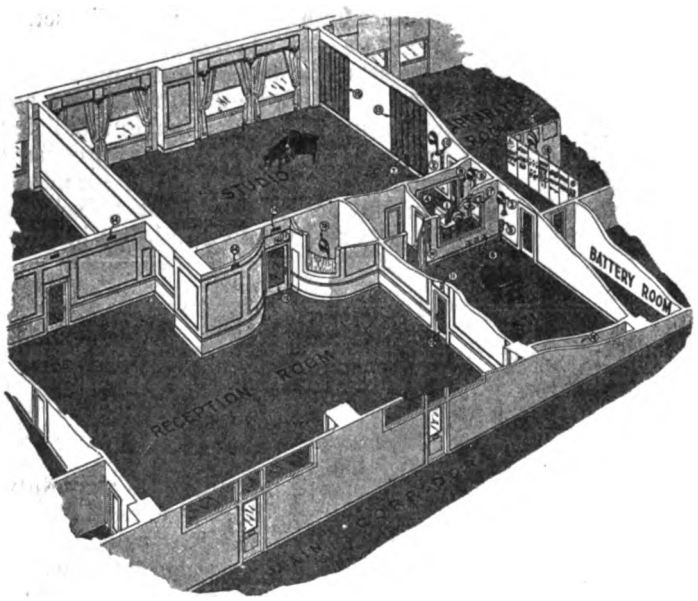
By Edgar H. Felix

COMPRISING the latest developments in studio acoustics, arrangement and technical improvements WEAF's new studio and remote control facilities in the Telephone and Telegraph Building at 195 Broadway, New York City, are the latest in broadcasting.

Minute attention to detail is responsible for much of the improvement in acoustic properties. The parquet floors are laid in pitch and are insulated from the walls of the studio. False walls are used between the studios and the hall to introduce a dead air space, making them practically impervious to sounds in the hall.

The draperies on the walls are so hung that they can be adjusted to give the correct degree of deadening. Heavy brass bands require more deadening than a quartette or a pianist. A speaking voice requires the least deadening for good transmission.

The paramount feature of the new studio installation



Isometric view of the new broadcasting layout of Station WEAF.

is the use of two studios, a small one for singers, speakers and small groups of instruments and a second large studio for bands, large choruses and orchestras.

The use of two studios will improve the running off of programs because it will obviate much of the delay to which the radio audience is subjected when single studios are used.

The accompanying illustration shows the arrangement of the new studios. The announcer's microphone (1) is located in a sound-proof booth having double plate glass windows and giving clear vision to both studios. Special walls render the booth impervious to outside interference. The loud speakers (2) and (3) in the studios repeat the announcer's introduction of the artists and also enables him to give directions regarding the placing of instruments and singers while the studio is idle. Switches on the announcer's panel (4) enable him to switch in his own microphone or those in the large and small studios (5, 6 and 7). There are two microphones in each studio, one regular and one emergency. The announcer's loud speaker (8) enables him to hear the performance as it is heard by his large unseen audience so that he gives his directions from the listener's point of view instead of a studio one. The signal lights (9 and 10) indicate by colored lights. whether the studio is on the air, the carrier wave is being sent out, the microphones are switched in or studio director or announcer are wanted on the telephone. Each door of the studios has a red signal light (11) which indicates that the particular studio is broadcasting at that time. If any one disregards this signal and opens the door when transmission is taking place, the loud speakers are automatically disconnected. As a further precaution the doors (12) are equipped with special knobs which can be opened only by one that is familiar with them. A loud speaker (13) concealed in a closet reproduce the entertainment for anyone in the reception room. A ventilation system (14) keeps the studios cool and well ventilated under all conditions. Adjustable deadening curtains (15) are readily adapted to suit the form of program being transmitted. A double wall with dead air space (16) prevents radiation of hall and elevator noises from the main corridor to the studio. The announcer who is the king of the whole situation is in direct communication with the engineers through line telephone (17). The equipment panel (18) is mounted with all necessary apparatus for controlling the microphone amplifiers and input currents to the special cables connecting the studio with the station as well as the station to outside points. Special equipment for equalizing lines to correct attenuation as well as instruments for measuring the gain of any amplifier or group of amplifiers are provided. Behind the panels is a large loud speaker (19) which provides the monitoring engineers with either the studio output or with the output of a loop receiver.

Radio Traffic in Italy Rapidly Increasing

The volume of radio traffic in Italy has increased at a surprising rate during the past four years, Trade Commissioner Osborne at Rome reports. In 1919, Italian statistics show only 50,000 words were transmitted, but it is now estimated that in 1923 this will increase to seven million words. This month a new station at Coltano, Italy, will be opened for commercial traffic and direct communication between New York and Rome will probably be established. Today this traffic is handled via Berlin, Paris or London.

Coming! New List of Broadcasters!

While the Department of Commerce has assigned wave lengths for each of the broadcasting zones established by the recent Second National Radio Conference, individual assignments of station wave lengths have not been announced. They are being arranged as rapidly as possible and as soon as finished A COMPLETE, UP-TO-DATE LIST OF BROADCASTERS will be published by RADIO WORLD.

The allocation of wave lengths for ten new Class A stations appears in this issue of RADIO WORLD.

New Jersey Radio Manufacturers Move for Stability in the Industry

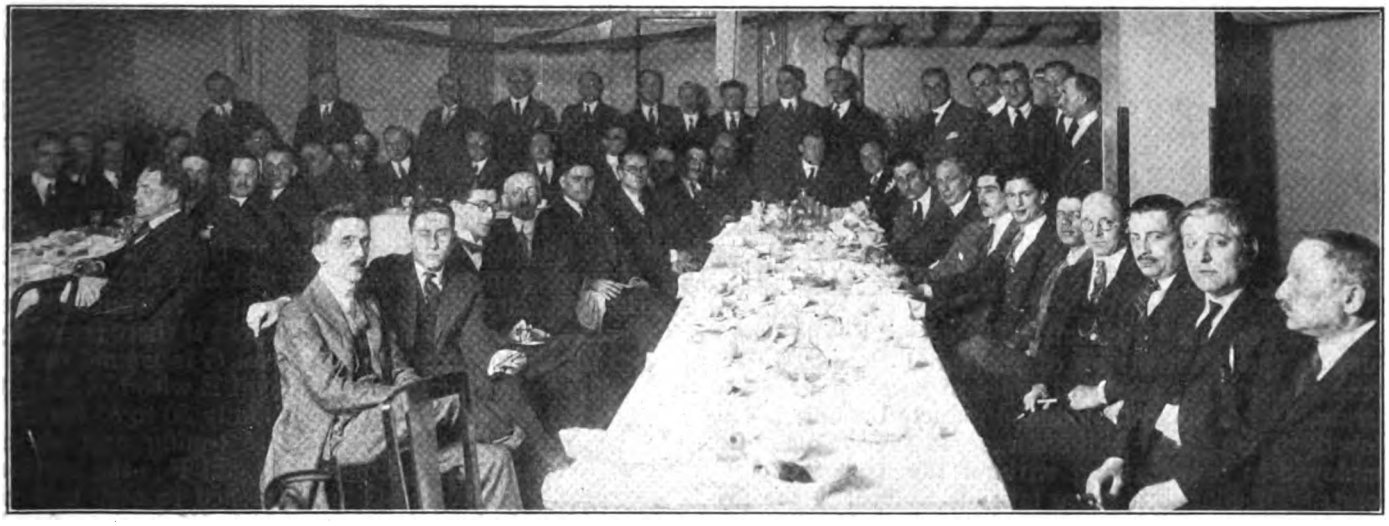
IT is an apparent fact that New Jersey is an important center of the radio manufacturing industry. During the past few years many of the largest and best equipped radio manufacturers have located in and around Newark, the big city of New Jersey.

Because of the tremendous growth of this industry during the period of the boom, and the consequent failure of many manufacturers when the market became flooded with inferior goods due to turning out quantity production rather than quality, it was thought a good plan to organize for the protection of the trade.

To stabilize the industry, keep it on a firm business basis and protect the reputable manufacturers, the Radio Manufacturers' Association of New Jersey was organized on April 5, 1923, with 31 reputable manufacturers as charter members.

The officers elected and who will serve until the end of the year are: W. S. Lefebre, Sheltone Mfg. Co., president; J. A. Harvey, Harvey Mfg. Co., vice-president; Ross Amos, Fibre Products Co., treasurer; H. L. Denburg, Royal Electrical Laboratories, secretary.

The charter membership of this organization includes the most active and reputable firms engaged in the business of manufacturing radio parts and sets, and is as follows:



Representatives of the radio industry at the dinner of the Radio Manufacturers' Association of New Jersey, Newark, N. J.

A. B. Cole Co., Newark; Adams Morgan Co., Upper Montclair; Ajax Elec. Spec. Co., Newark; Daven Radio Co., Newark; Davis Radio Co., Keyport; Diamond Spec. Co., Newark; Duranoid Co., Newark; Eagle Radio Corp., Newark; Essex Spec. Co., Berkley Heights; Fibre Products Co., Newark; Lloyd Gehman, East Orange; Harvey Mfg. Co., Newark; Mack Moulding Co., Little Falls; Metro Elec. Co., Newark; Multiple Elec. Prod. Co., Newark; Mydar Co., Newark; Murad Laboratories, Asbury Park; Newark Spinning & Stamping Co., Newark; Radio Detector Co., Newark; Royal Electrical Laboratories, Newark; Shamrock Mfg. Co., Newark; Shaw Insulator Co., Irvington; Sheltone Mfg. Co., Newark; Standard Crystal Co., Newark; Standard Metal Co., Newark; Standard Radio & Equipment Co., Newark; Thresher Radio & Mach. Co., Newark; Union Radio Co., Newark; United Specialties Co., Newark; W. B. L. Radio Co., Newark; Woodside Mfg. Co., Newark.

As reported in RADIO WORLD last week, a combined business meeting and dinner was staged by the Radio Manufacturers' Association of New Jersey and the Radio Trade Association at the St. Francis Hotel, Newark, on the evening of April 26. In the accompanying illustration is portrayed the attendance at the dinner which included the following gentlemen:

C. B. Cooper, Crosley Mfg. Co., 1803 Tribune Bldg., New York City; H. C. Gawer, R. C. A., New York City; W. S. Lefebre, Sheltone Co., Newark, N. J.; John A. Harvey, Harvey Mfg. Co., Newark, N. J.; W. E. Harkness, A. T. & T. Co., New York; George F. McClelland, A. T. & T. Co., New York; William R. Brogh, W. B. L. Radio Co., Newark, N. J.; Otto Herschkowitz, Ajax Radio Corp., Newark, N. J.; Jack Larson, W. B. L. Radio Co., Newark, N. J.; A. R. Mortan, Clapp-Eastham "Radak," 395 Broadway, New York City; W. H. Frasse, Daven Radio Co., Newark, N. J.; P. W. Golden, A. B. Cole, Inc., Newark, N. J.; T. F. W. Meyer, Mydar Radio Co., Newark, N. J.; L. E. Gehman, L. E. Gehman & Co., Newark, N. J.; G. A. Thomson, Diamond Elec. Spec. Corp., Newark, N. J.; F. M. Rosenfeld, Diamond Elec. Spec. Corp., Newark, N. J.; Harvey Mansfield, Radio Broadcast, Garden City, N. Y.; Arthur H. Lynch, Radio Broadcast, Garden City, N. Y.; F. M. Artley, Artley Products, Inc., Jersey City, N. J.; R. E. Perrin, Artley Products, Inc., Jersey City, N. J.; Mortimer Salzman, Wholesale Radio Equip. Co., Newark, N. J.; D. McCormack, Radio Supplies, Newark, N. J.; W. B. Curtiss, Curtiss Radio Sales Co., Newark, N. J.; H. R. Rose, Shamrock Mfg. Co., Newark, N. J.; D. W. May, D. W. May, Inc., "W. B. S.," Newark, N. J.; F. Russell, Shamrock Mfg. Co., Newark, N. J.; D. Wald, Wald Electric Co., New York City; Charles A. Gould, Gould Storage Battery Co., New York City; O. H. Caldwell, Electrical Merchandising, New York City; H. L. Denburg, Royal Electrical Laboratory, Newark, N. J.; A. Rubin, Henry Hyman Co., 476 Broadway, New York City; B. Muldoon, Henry Hyman Co., 476 Broadway, New York City; E. Anglin, Henry Hyman Co., 476 Broadway, New York City; L. A. Nixon, The Radio Dealer, New York City; M. P. McNeely, The Radio Dealer, New York City; D. S. Walker, Harvey Wire Co., Newark, N. J.; James P. Black, Harvey Wire Co., Newark, N. J.; Ralph Coen, The R. C. Mills-The R. C. A Remarkably Good Selective Receiver

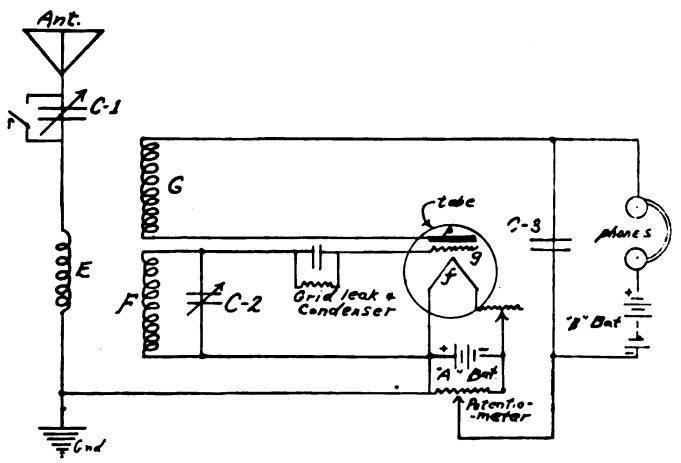
By C. White, Consulting Engineer

THE results that can now be obtained with a well-made single circuit regenerative tuner are really nothing short of remarkable. But the users of such outfits in some cities and certain localities are experiencing quite a bit of trouble with interference. It is, indeed, sad that the single circuit tuner has not the selectivity of the more complex types, for without doubt it has good volume. Then again, a single circuit tuner will pick up more interference from your neighbor's set than a coupled circuit tuner. Aside from the fact that a single circuit is simple to operate one of the most potent reasons for its popularity is its economy. The triple circuit tuner with its two variometers and a variocoupler to start with costs more than the best type of single circuit affair. Yet if the ambitious radio fan will take his time and patience he can actually build a triple circuit tuner for the same



Connections for the tuner and hook-up of Mr. White's selective receiver.

cost as a good single circuit. The secret of the whole thing is the construction of the tuner elements. Instead of using the standard types of variocouplers and variometers, a special combined inductance unit is employed. The coupler will embrace all the wavelengths employed in broadcasting without the use of switch-points. Of course, if more latitude is desired the primary can be loaded by means of honeycomb coils.

In the illustration herewith is shown the connections of the tuner. The primary circuit can either be tuned or untuned depending upon the type of signal and the amount of selectivity desired. A tuned primary will give greater selectivity. The secondary is likewise tuned, still further increasing the selectivity of the tuner. Although tuning the secondary by means of a condenser instead of a variometer is not as desirable, yet owing to the quiet operation of the former and the saving of time in adjusting for operation, I certainly think that the sacrifice is justifiable. The ordinary three circuit tuner is too selective for the average novice to operate with ease, while a single circuit removes this trouble but adds the one of poor tuning. This receiver lies between the ordinary single circuit and the standard triple circuit in sharpness of tuning. The constants of the circuit are as follows: The condenser C-1 is a 23 plate air variable, C-2 is an 11 or 13 plate air variable, and C-3 is a .002 mfd. mica condenser used as a bypass. The size of grid leak and condenser will depend solely upon the tube used, but, as a general rule a .00025 mfd. condenser with a two megohm leak will suffice for most cases. It is very desirable to procure a mica condenser and a good grid leak in order to insure quiet operation.

Owing to the fact that there are so many different types of detector tubes upon the market it is of the strictest importance to see that the filament rheostat has a resistance large enough to give ample room for gradual and steady filament control. Do not try to operate a UV-199 tube with a six ohm resistance for a rheostat and expect to get very wonderful results. As a good rule of thumb it is well to remember that the resistance of a rheostat should be about the voltage rating of the tube divided by the rated filament current of the tube. For an example, the new UV201-A radiotrons have a filament rating of .25 ampheres at five volts. Dividing five by .25 we get 20 ohms as an approximate resistance for the filament rheostat. Remember that the figure is only approximate but it is obvious from the little calculation that a six ohm rheostat will not do the trick in the right way. A potentiometer of 250 or 300 ohms is employed to smooth out the regenerative adjustment thus adding increased stability to the tuning in of distant and weak stations.

As I previously have stated the trick to the economy of this particular three circuit receiver is the construction of the tuning element E, F, and G. The coil E is wound with No. 22 D.C. magnet wire on a good molded bakelite or formica roter. It should have about 40 to 50 turns. The coil F is stationary and is wound on a four-inch bakelite or formica tube. It should have about fifty turns with No. 22 D.C.C. wire. This coil should be wound with the wire spaced apart. This is best accomplished by winding the wire with a piece of cord between each turn of wire and the next, shellacing the finished coil and removing the cord when dry. This arrangement spreads the coil and decreases disturbed capacity, the foe of selectivity. It would be well to wind the coil E in a similar manner if there is enough room on the rotor form. The coil G is wound on the same type of rotor form as the coil E with No. 22 D.C.C. magnet wire likewise, but has only 30 to 35 turns.

The assembly of the complete tuning unit should be as follows: The secondary or coil F is the stationary form, coils E and G are attached to each end respectively of the tube upon which W is wound. In other words the unit looks just like a standard variocoupler which has two rotors, one at each end of the stator tube, instead of one at one end only. Care should be taken in the mechanical construction to see that the two rotors do not touch when moved. The tube should not only be long enough to prevent this, but also for ample fastening of the rotor shafts on to the tube at each end. The coupling between the secondary and the primary can be adjusted separately from the tickler coupling. If the primary were made the stator then the secondary would be movable, and when the secondary and primary coupling would be changed the tickler coupling would be altered in the same amount approximately.

DO YOU WORK IN A RADIO FACTORY?

If so, it would pay you to represent RADIO WORLD. Get subscriptions and earn a generous commission for doing so. Everybody connected with your concern, from the boss down to your fellow employees, should read RADIO WORLD every week.

"This Is Station WGY Schenectady" —Its Powerful Equipment

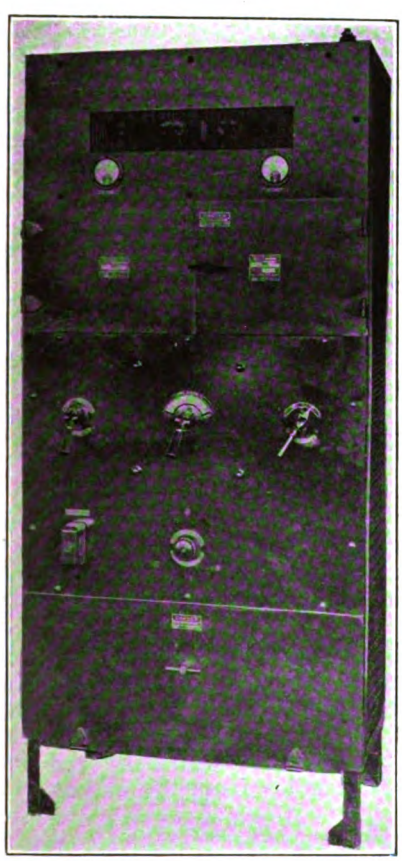
By Robert L. Dougherty

TO many broadcast listeners, station WGY, General Electric Company, Schenectady, N. Y., does not need any introduction. It will be of interest to readers of RADIO WORLD, however, to know that this powerful station has practically covered the entire Western Hemisphere. Its western record is Hawaii, a distance of over 5,000 miles direct air-line, and its eastern record is Paris, France, a distance of 3,225 miles. Its southern record is Peru, a distance of 3,230 miles.

The apparatus in this marvelous broadcasting station, since its installation 12 months ago, has been constantly changed to eliminate all objectionable features in an effort to make it one of the most powerful in the land.

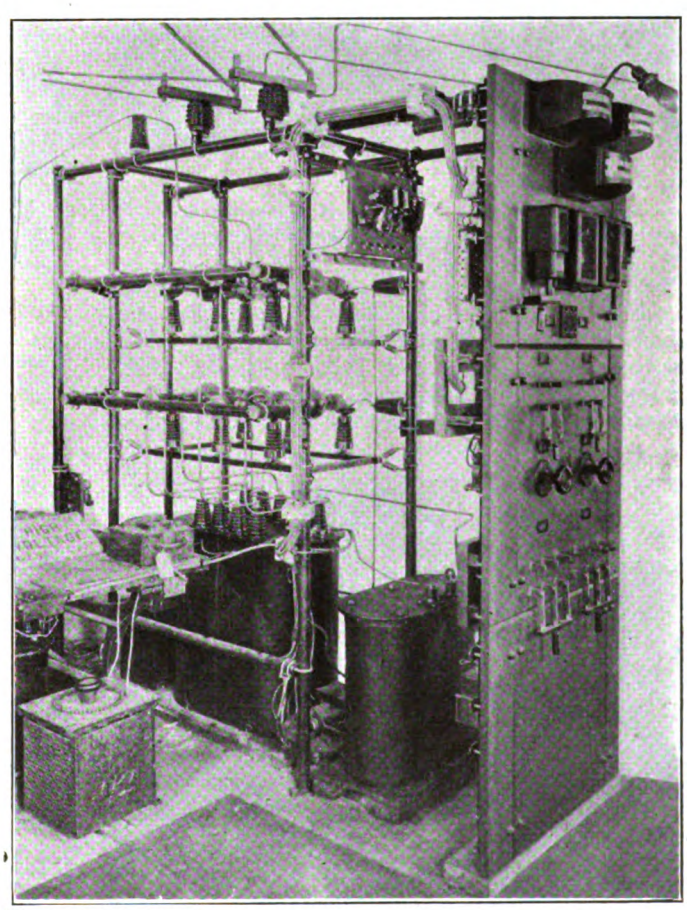
ing of time signals. In order successfully to accomplish this, WGY uses the apparatus shown in Fig. 4. This consists of a special trap circuit, shown on the extreme left hand, a tuning unit next to it, and a special set of amplifiers, with a power amplifier, at the end to boost the current, which is then transmitted directly into the set by means of a loud speaker.

In order to broadcast services from the different churches and institutions, it is of course necessary to have separate control at the place where the service or program takes place. This instrument is shown in Fig. 3. With this apparatus the man located at the transmitting end is enabled to control perfectly the program as to modulation and loudness before it is sent over the land lines to be further amplified and



(C. Photonews, N. Y.)

Fig. 1—1-KW transmitter panel, such as used at WGY, Schenectady, N. Y.



(C. Photonews, N. Y.)

Fig. 2—Kenotron assembly panel, used to supply 12,000 volts D.C. to the plates of the tubes.

Fig. 1 shows the 1-kw transmitter control panel as now used by this station. With this panel either CW, ICW or telephone may be used at the will of the operator. It employs four 250-watt radiotron tubes—two as oscillators and two as modulators—with two 50-watt radiotrons as speech amplifiers. The current for this panel is supplied from a three-unit motor-generator. It is a double-current self-excited generator and a high-voltage direct-current generator, driven by a single phase direct current motor, supplied from a 110-volt line.

This station is particularly successful in the relay-

then broadcast, by means of the regular station equipment. By this method finer adjustment is possible and the man at the transmitter of the station does not need to bother with anything else but the fact that the amplifiers, and broadcasting transmitter are functioning satisfactorily. Such equipment as this is getting to be quite common in the cases where the actual performers are located at a great distance from the studio, and it is by the use of such apparatus as shown that perfect modulation and transmission can be obtained, with the least amount of trouble and the conditions

(Continued on next page)

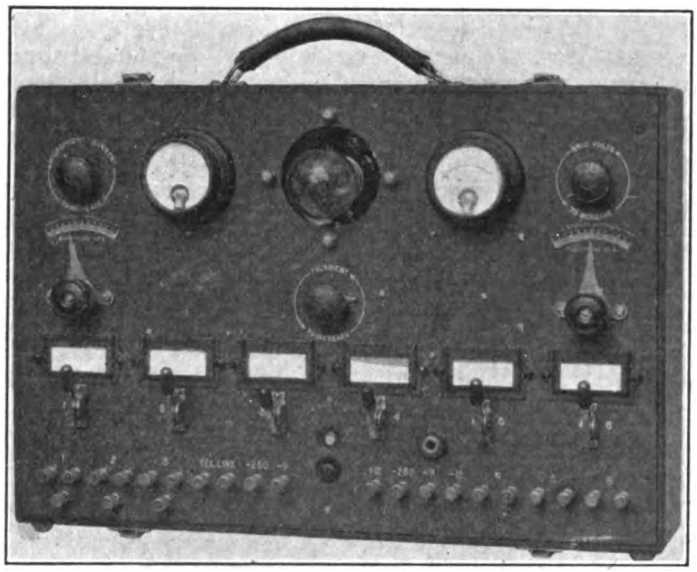
(*Concluded from preceding page*)

along the line changed, to suit the nature of the performance.

When this station is operating on full power, 12,000 volts must be supplied to the plates of the tubes. This is done by the kenotron rectifier shown in Fig. 2. In the rectifier the delta-connected primary is supplied from a three-phase 220-volt generator. The high tension windings of the transformers are connected to form two Ys, 180 degrees out of phase. Each Y, with its rectifying tubes (kenotrons), is thereby a half-

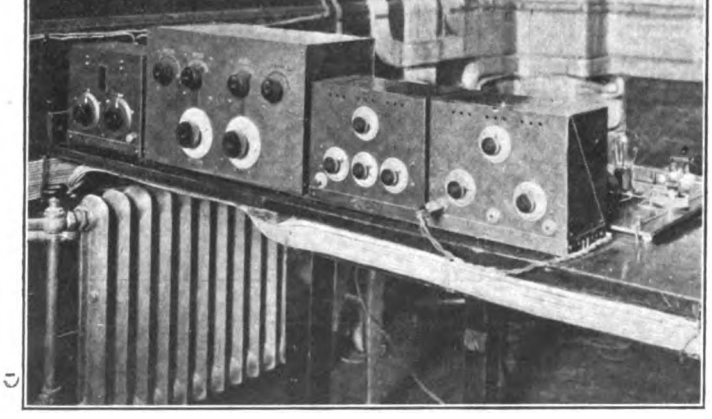


(C. Photonews, N. Y.)

Fig. 3. Church control system panel. Used where a program is to be broadcast from a distant point and no amplifying system is present.

wave rectifier. There are six kenotrons used in this set, the holders for which are directly back of the board. This rectifier will allow 12,000 volts to be supplied to the plate current, but with a ripple effect of less than one-tenth of one per cent.

The oscillator and modulator assembly is illustrated in Figure 5, and utilizes a tank circuit loosely coupled

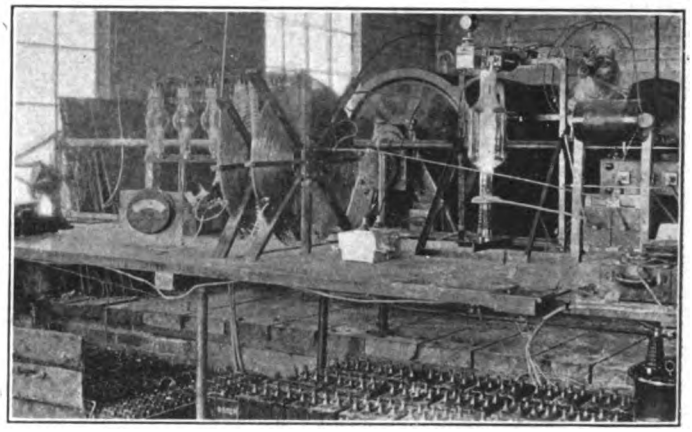


(C. Photonews, N. Y.)

Fig. 4. Time signal transmitter and amplifier used to retransmit time signals from the Naval Observatory, Washington, D. C.

to the antenna in such a manner that the frequency is determined by the constants of this tank, or dummy circuit. The oscillator uses one tube (UV-208) which is operated at reduced output. It is shown in the right center of the illustration. The modulating system employs five tubes (UV-206) and the plate method of modulation is employed.

People listening to a broadcast program do not realize the extreme care and accuracy that must be used in order to furnish them with a well worked out and transmitted program. Before the station opens, the staff is all on hand, and all clocks are checked to the second, as the studio where the actual performers sing or talk is located at a distance from the control and transmitting room and no mistakes as to time can be allowed. Before the actual operation of the station, the power men throw the complete assembly of operating apparatus to a dummy antenna and carefully check all readings. Then the apparatus is switched on the antenna, and a signal from the power house (located at distance of 3,000 feet from the operating room) tells the operators that everything is in readiness from an operating standpoint. When the program is started, the men at the power house listen in and tell the operators and the man in charge of the studio whether the modulation and signals are perfect; if not, they are immediately corrected. For every different kind of program a different type of microphone



(C. Photonews, N. Y.)

Fig. 5. Modulating and oscillating equipment. One oscillator and five modulating tubes are used. The oscillator is shown in the right center of the illustration and the modulators are directly to the left of the tuning system.

must be used and also the modulator system rechecked. This is done to conform with the amount of power necessary as it requires more power to transmit a vocal solo properly than it does to transmit a band or dance orchestra. Checking is constantly going on, and listeners at a distance cannot realize the activity that is necessary to transmit a program that they will receive perfectly.

WGY was the first station successfully to use the pallophotophone in the re-transmission of talks by famous persons. The first test on this marvellous device was heard and recorded in London, England, and Paris, while the person who delivered the address was many thousand miles from the actual transmitter.

Important Notice About Change of Address

Owing to the increase in circulation of RADIO WORLD and the fact that we have to go to press earlier, it is necessary that all changes in subscribers' addresses should reach us two weeks before date of publication. If you are going away, or contemplate changing address in the near future, please send in your change at once.—Subscription Dept., RADIO WORLD, 1493 Broadway, N. Y. C.

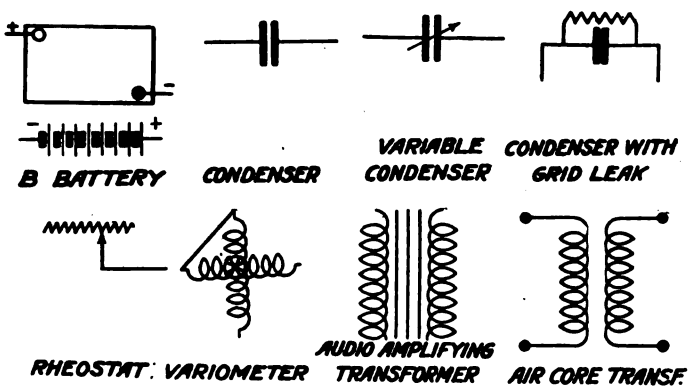
Elementary Instruction for the New Army of Radio Beginners

Constantly Used Terms Explained in Plain Language for the New Radio Enthusiast

By Lynn Brooks

RHEOSTAT: An instrument used to reduce the amount of current flowing in a circuit. It is found in numerous forms, but the type with which we are concerned is that which varies the filament current. Generally it consists of a number of turns of german silver or other high resistance wire wound on a former which is circular or semi-circular in shape. Contact and variance of the resistance are made by means of a slider which passes over the wire. The rheostat sometimes takes the shape of a pile of carbon discs which are either compressed or released by means of a screw arrangement. When they are tightly compressed the resistance is very low and increases as the screw is released, reaching its maximum resistance when the carbon discs are as loose as possible.



Symbols used in drawings of radio apparatus to indicate the various parts.

VOLT: The measure of pressure or electromotive force, in an electrical circuit. Discovered by Count A. Volta, an Italian electrician. When measuring pressure, such as that caused by water flowing in a pipe, we would say that the pressure was so many pounds per square inch of surface. In electricity we measure the pressure in volts. A volt is the force necessary to cause a current of one ampere to flow through a circuit having a resistance of one ohm.

COULOMB: The time measure of "quantity" as related to electrical current. Discovered by C. A. De Coulomb, French scientist. It is the quantity of electricity that will pass a given point in an electrical circuit in one second. To measure coulombs it is necessary to measure the quantity of electricity delivered by a current having a strength of one ampere flowing for one second of time. Thus, a current of one-fifth ampere must flow continuously for five seconds to deliver a coulomb of electricity. A current of 10 amperes flowing through a conductor for one second would thus be 10 coulombs of electricity.

AMPERE: The measure of current flow in an electrical circuit. Discovered by A. M. Ampere, French scientist. An ampere is the current resulting from overcoming a resistance of one ohm in an electrical circuit under the pressure of one volt. Thus to find the amperage in a circuit it is necessary to divide the voltage by the resistance—the result being the amperage of the circuit.

WATT: The unit of electrical energy or power. It is the product of the voltage and current in a circuit when there is one volt and one ampere in the circuit. A horse-power equals 746 watts.

FORMULAE: For determining the voltage of a circuit use this formula: Voltage = Amperage multiplied by Resistance.

Problem: Known resistance 6 ohms. Known amperage two amperes. Find the Voltage. Amperage X Resistance = Voltage. 2 X 6 = 12 volts in the circuit.

For determining the amperage in a circuit use this formula: Amperes = Voltage divided by Resistance. Problem: Known voltage 12. Known Resistance 6 ohms. Find the amperage. Voltage ÷ Resistance = Amperage. 12 ÷ 6 = 2 Amperes in the circuit.

For determining the resistance in a circuit use this formula: Resistance = Voltage divided by Amperes. Problem: Known Voltage 12. Known Amperage 2. Find the resistance. Voltage ÷ Amperage = Resistance. 12 ÷ 2 = 6 Ohms resistance in circuit.

For determining Watts in a circuit: Watts = Volts X Amperes. Problem: Known voltage 12. Known amperage 2. Find the watts. Voltage X Amperage = Watts. 12 X 2 = 24 Watts in the circuit.

Radio Produces Piano Music from an Organ

By Jean Franklin

WHILE calling upon a prospective customer recently I saw a little child seated at an old organ and yet the music was that of a piano, which led me to ask questions. The big brother had purchased the old organ from a second-hand dealer for $5.00 and brought it home. Every one jeered at him and at his purchase, but "the way of the truly radiophan is hard"; so he kept his counsel and packed the old organ to his workshop. Here he removed carefully the scroll woodwork above the stops, set in his bakelite panel, and behind this installed his radio set.

The organ possessed a roll top and when the radio is not in use, he rolls down the top and secures it from dust and dirt. The set did not interfere with the mechanism of the organ in the least and he later had carved an aperture in the bottom beside the pedals, and here he has placed his loud speaker.

For my entertainment the sister, who was an excellent musician, was called in and she accompanied on the organ the voice that was singing via the radio. The happy little family also told me of sending in a request to sing one of their favorite numbers one evening. The request was complied with by the broadcasting station and the daughter accompanied the musicians who were playing so far away and the other children sang the same melody.

As I left the happy household, the little mother explained to me that previous to the advent of radio in their home, one daughter spent her evenings in a dance hall on the other side of town, her sons in a pool hall, and her husband at his store; but now the family hurried through supper and had their friends come in to hear the concerts.

(C. Kadel and Herbert)
Thousands of people have enjoyed listening to the organ recitals broadcast from Station WEAF every Sunday, but few have had a chance to see the monster organ. Here is shown the manual of the Skinner organ, which has 3,500 pipes, 44 stops and all horns, chimes, harps and full equipment. It cost over $50,000.00 to install. William E. Zeuch, noted organist, who has entertained thousands, is shown playing.

(C. Kadel and Herbert)
The speech amplifier control used to modulate the Skinner organ recitals before they are sent over the land wires to the operating room of WEAF. Because of the great volume of sound produced by an organ on the deeper tones it is necessary to regulate the apparatus extremely carefully if perfect reproduction is to be obtained.

(C. Keystone Views)
The boys of Dr. Bernardo's school, London, England, were recently presented with the set illustrated, to enable them to listen in on the Paris and New York broadcast programs. The photo shows Lady Torrington, its donor, listening in on one of the New York programs.

(C. Photonews, N. Y.)
Charles Ray letting his "pet houn' dog" listen in. "Whiskers" evidently doesn't think much of the soprano concert being broadcast and is just about to let the world know by a prolonged wail of protest against all soprano singers in general and that one in particular.

(C. Harris and Ewing)
First and exclusive illustration of Surgeon General Hugh S. Cumming, of the United States Public Health Service, in the radio room at Health Headquarters, Washington, D. C. This service is devoted exclusively to broadcasting health lectures on how to cure and prevent disease. The broadcasts are relayed through regular land wires to the Government broadcasting station at Arlington. These health talks are sent out twice a week, and arrangements are being made to increase the service until forty stations, covering the entire United States, are broadcasting them.

(C. W. T. Meyers)
Powell Crosley, Jr., President of the Crosley Manufacturing Co., Cincinnati, new equipment of Station WLW. The transmitter on his right is the new Electric control board. The speech modulator and amplifier is located directly of the operator, who has ample means of listening in on the program and cha tions to suit the needs.

(C. Wide World Photos)

The proprietor of the "Butchers' Arms," Cross Land, Salford, England, has installed a complete receiver to keep his customers busy and buying. No, Oscar, the glasses do not contain root beer, as soft drinks are taboo in that particular atmosphere, even though they do use soft tubes as detectors. Who wants to be proposed for the next election as chief broadcaster and announcer in Great Britain? Now, one at a time—one at a time!

(C. Photonews)

Douglas Fairbanks shows how Robin Hood, the Merry Outlaw of the Twelfth Century, might—I said might—look if you could persuade him to get close enough to a modern Magnavox while a broadcast program was going on. They must be announcing a funny joke to make a busy man like Doug smile that way. Oh, well, radio does relieve once in a while. Who is it Doug? New York or London?

(C. Fotograms, N. Y.)

The last word in convenience has at last been made, thanks to radio. You can now reserve your seats in B. F. Keith's Royal Theatre, New York City, via radio. Miss Theresa Mardigan, operator, is always willing and ready to take your order over the air, and she can't talk back and say "sorry," either. Say, fans, notice the little old loose coupler all by its lonely? How well do I remember——!

...dicating the ...tt Western ... to the desk ... the condi-

(C. Harris and Ewing)

The latest code invention, which is capable of 11,881,376 changes by the mere twist of that little dial on the left-hand side of the machine. It is used by the U. S. Government instead of the bulky lead covered code books which were always such a temptation to the secret agents of other governments.

(C. Wide World Photos)

London has really gone radio mad, don't you know. They are now putting receiving sets on the private cars of the elite, so that they won't even miss a word while they are rushing to their offices.

(C. Kadel and Herbert)

"Let them that wants to dance themselves into a fit do so," is Mr. Harold Stein's motto. He is out after the "Radio Golf" endurance record for continuous reception. Mr. Stein has covered 30,000 miles in 24 hours' continuous listening in and claims to hold the record. Now, who is going to beat him? Send all records to Harold Stein, 1048 Madison Avenue, New York City.

RADIOGRAMS

WORLD NEWS HAPPENINGS BRIEFLY PHRASED FOR BUSY READERS

Dr. Lee de Forest, the well-known inventor, sailed for Europe last week.

* * *

An electrical cure for pneumonia is being perfected. The patient is shocked out of his congestion. Ordinarily, observes the Minneapolis Journal, he does not get the doctor's bill in time for the necessary shock.

* * *

The Heraldo De Cuba, a Spanish daily newspaper published in Havana, Cuba, will be the first newspaper on the island to own and operate a radio broadcasting station, which it expects to place in service about May 15.

* * *

The first baby born on the Government reservation at the radio station at West Sayville, Long Island—a boy—has been christened Francis Arthur by his parents, Mr. and Mrs. Robert A. Maxwell. The baby was born on Friday, April 13.

* * *

Action on regulation of radio communication is being discussed at the Pan-American Congress in session at Santiago, Cuba. The United States delegation is recommending the early convocation of a Pan-American Radio Conference in Washington.

* * *

In order to give advance information, WGY, the General Electric Company's broadcasting station at Schenectady, N. Y., a general outline of each week's programs will be announced on the preceding Friday at the close of the early evening concert—about 9:30 p. m.

* * *

Radio was employed to divert a patient's attention as an aid to local anaesthesia by surgeons at a New York hospital last week during an operation. The operation was successful and it was admitted that radio might in future become a factor in similar operations.

* * *

Floyd Charles Furlow, president of the Otis Elevator Company, died in New York City last week. He was educated at Georgia Institute of Technology and Worcester Polytechnic Institute. He was an early experimenter with X-rays, and built the first wireless apparatus in the South.

* * *

The results for the Einstein eclipse problem have just been deduced from the photographs secured at Walhal on the northwest coast of Australia on September 21 of last year by the William J. Crocker eclipse expedition from the Lick Observatory, University of California. These results are reported to be in exact accord with the requirements of the Einstein theory of relativity.

* * *

The Eiffel Tower will last another twenty-three years, according to engineers who have been examining its stability in consequence of a report that it was falling down. During the war the tower paid for itself many times over as a wireless information station controlled by the war department. It continues to be used as a wireless station, and broadcasts an evening concert and news bulletins that may be picked up at many points in Europe and on the Atlantic.

* * *

Earl Morrison, a parole violator, has been returned to the penitentiary at Joliet, Ill., following his capture by Freeport, Ill., police on a "radio tip." Morrison was paroled to a Chicago Heights business man last September. He left there a few days ago, saying he was going to Chicago. A description of Morrison was broadcast by Radio Station WOC, at Davenport, Iowa. A sergeant of the Freeport police station who was listening in copied Morrison's description.

* * *

"The concert was good and its reception perfectly clear and remarkably loud," says Louis M. Royal of Wrangell, Alaska, in a recent note to the operator of KFAE, broadcasting station at the State College of Washington, at Pullman, Wash. And L. L. Kannaly of KAN Ranch, Oracle, Arizona, responds with: "KFAE was appreciated in Arizona last night, and all hands on the KAN wish to thank you." As far east as Peoria, Ill., R. G. Coleman picked up the college with a short-wave regenerator set with two steps of amplification.

* * *

The practical use of radio, the airplane and modern birds-eye photography was strikingly demonstrated one day last week by the Marine forces at their main Atlantic Coast base at Quantico, twenty miles down the Potomac from Washington. Fire in a group of ten former Shipping Board wooden vessels was discovered. Through powerful field glasses, officers at Quantico, gazing down the Potomac, discovered the fire. They sent a marine aviator to investigate. He photographed the burning ship, sent the information by radio to Quantico, on the basis of which assistance was given to combat the fire, and the completed pictures of the fire were delivered in Washington in time to be printed in afternoon newspapers.

* * *

More than half a million people, it was estimated, last week heard the first radio debate on the prohibition question that has been held in this country. The debaters were Wayne B. Wheeler, general counsel of the Anti-Saloon League of America, and Colonel Ransom H. Gillett, general counsel of the Association Against the Prohibition Amendment. The arguments were broadcast from the studio of the American Telephone and Telegraph Company's station WEAF, where the debate was held. The point furthest away known to have received the discussion was a radio receiving set in Petersburg, Va. More than 150 questions were received by telephone, local and long distance, and hundreds of additional calls could not be handled.

Ten More Class A Stations Licensed

THE Department of Commerce has licensed ten more broadcasting stations to operate under Class "A" on specific waves in their respective districts.

Kansas, Nebraska, Missouri and Louisiana each received two stations, while Oklahoma and Texas got one each. Among the new stations listed below with their wave lengths, calls and power, are a daily paper, a church, two universities, a National Guard unit, and three electrical and radio concerns, showing an unusual distribution.

Although three of the stations received the same wave length, it will be noted that they are all in different districts and states, separated so interference will not be marked.

The ten new Class "A" stations which follow were licensed during the week ending April 28th:

Call	Station	Fre'cy. Kc/s	Wave L'gths. Meters	Power Watts
KFGM	Abilene Daily Reporter, Abilene, Texas.	1290	233	100
KFHF	Central Christian Church, Shreveport, La.	1130	266	150
KFGP	Cheney Radio Co., Cheney, Kansas.	1310	229	10
KFHI	Dixon, Charles V., Wichita, Kansas.	1340	224	20
KFGV	Heibreder Radio Supply Co., Utica, Neb.	1340	224	10
KFGC	Louisiana State University, Baton Rouge, La.	1180	254	100
KFFX	McGraw Co., The, Omaha, Neb.	1080	278	250
KFGJ	National Guard, Missouri 138th Infantry, St. Louis, Mo.	1130	266	100
KFHC	University of Oklahoma, Norman, Okla.	1180	254	20
KFHD	Utz Electric Co., St. Joseph, Mo.	1330	226	10

Answers to Readers of Radio World

Would different rheostats in the Grimes reflex circuit be of any advantage? I am using different makes of tubes and they consume different values of current. Can this circuit be used on an outside aerial with a tuning inductance? Can the R215-A peanut be used in this circuit?—A. D. Turnbull, 57 Union Street, Sydney, N. S., Canada.

You can use rheostats in each tube filament circuit if you wish. The only reason that this was eliminated in the original circuit was that it made the controls simpler and that is what they are striving for. You can use this circuit in a tuned antenna circuit by connecting the secondary of your coupler across the two terminals where you normally connect your loop. You can use the tube you name with this circuit.

* * *

Kindly furnish me with a hook-up for using one WD-11 with a loop. I do not want to use any variocouplers or tuners unless it is absolutely necessary, as I intend to put it in a canoe and want to make it as simple as possible. Will the circuit enable me to tune in local stations and distant ones also? —L. Robinson, 535 West 189th St., New York City.

The hook-up you desire is given herewith. It will work on the canoe but its range is necessarily limited and you can not expect

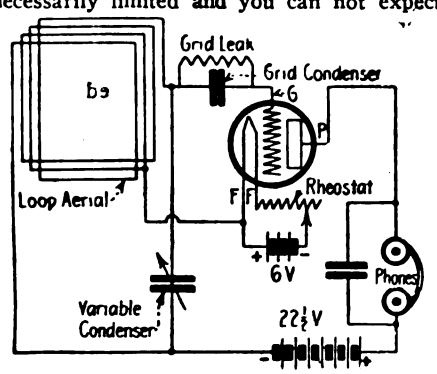

Diagram requested by Mr. L. Robinson. This circuit allows reception on a loop without the use of any inductances. The variable condenser is .0009 mfd.

to do any extensive long distance work with it. For local work it will be perfect. The loop should be about two feet square wound with litz or stranded wire. Ten turns will be about right. Use a clip for the third connection and do your rough tuning with that. You will then be able to incorporate all your apparatus in a box 6x6 inches, with the batteries separate.

* * *

Does it make any difference in the reception of signals if the antenna is hung loose, as long as the proper amount of wire is used?

I want to build a set using the peanut tube. What apparatus will I need?—Joseph P. Sims, 3826 Hennison Place, N. W., Washington, D. C.

The manner in which the antenna is erected does affect the reception. Be sure, however, that it will not swing and touch anything like telephone poles, electric wires, high tension lines or tin roofs. It will allow better reception if it is strung tightly.

The apparatus you will need is a tuner, condenser, both A and B batteries, variable condenser, telephone condenser, rheostat, socket, phones, antenna wire, and insulators.

* * *

Our local dealer claims that the U. V. 201A cannot be used for radio frequency. I have heard many reports to the contrary, but wish to find out definitely before constructing my set. Can they be used with the Acme R2 transformers? Are they good detectors? Are they good amplifiers? I wish to do away with my present set and install a one step radio detector and two stages of audio frequency. What bulbs may I use? I have 201A. My antenna is 70 ft. of wire strung around the picture moulding and with this I can only receive WJZ and other local stations. Does it matter if the power lines for my house are on a level with my antenna? Would this tend to decrease my distance?—Emil Nyldert, 389 George St., New Brunswick, N. J.

You have been misinformed. These tubes will work with radio frequency. They are perfect detectors and amplifiers. They will work in any circuit as either audio-frequency amplifiers, detectors or radio-frequency amplifiers. The transformer you mention is O. K. for use with this tube. You may use the 201A tubes in the circuit you mention. There may be a slight absorption noticed when such an antenna is installed, but if the wire is insulated it should not prevent you from receiving distant stations if your receiver is a tube set. Have it well insulated and do not run it near metal such as beams or posts. Good results have been achieved using a wire strung around the moulding such as you describe.

* * *

I have constructed the one tube super-circuit described by W. S. Thompson on page 9 of Radio World *for March 17. I have used the same values specified and hooked it up as shown but cannot get anything but a loud hum like that of a generator. What can my trouble be and how can I remedy it? —F. H. Flood, Chelsea, N. Y.*

The fact that you get a loud hum seems to suggest the fact that you have an open connection at some point in your circuit. Go over your wiring very carefully, examining all the connections and testing out the honeycomb coils. It may be that there is a broken connection in the honeycomb and that would cause it. See that your tube is making good connection on all the contacts. Watch the connections on your jacks and examine your variometer to see that there is no open connection in it. Rewire your set, being sure that you follow the diagram exactly. Look at all your fixed condensers and test them for a blown condenser as this might also be the cause. Mount the coils at right angles to one another. Examine the honeycomb mount to see that it is making good connection all around. This hum should not be present if the set is correctly wired and all connections soldered and no open line exists.

* * *

In the Anniversary Number of Radio World *you state in connection with the constructional article on a variocoupler, that a bank wound coil will transform this tuner into a multi-wave tuner. Where can I obtain information on this type of winding?—Joseph M. White, 2731 W. Silver Street, Philadelphia, Pa.*

If you will refer to Radio World for March 10, 1923, you will find an article on bank winding and the methods used in making bank wound coils on page 8 in an article by Arthur S. Gordon. It is very comprehensive and the drawings illustrate it clearly.

* * *

Kindly give me the diagram of the Reinartz circuit and also some information on the coils.—J. A. Thorne, 37 Riva Ave., Milltown, N. J.

If you will refer to page 23 of Radio World for January 13, 1923, you will find a circuit diagram of the receiver you mention, as well as a complete description of how to wind and tap the coils.

* * *

Can I use the two High-Mu audion tubes in place of the regulation U. V. 201 tubes in the reflex circuit described by W. S. Thompson? Can any radio-frequency transformer be used with these tubes?—F. H. Ameel, 88 Grand Ave., Mt. Clemons, Mich.

You can use these tubes in this circuit with success. You can also use any radio-frequency transformer, but it is better to use the Meyers as it is constructed for use with those tubes and calculated to the internal characteristics of the Meyers tubes.

* * *

Kindly give me a hook-up for the connection of a series-parallel switch in the antenna

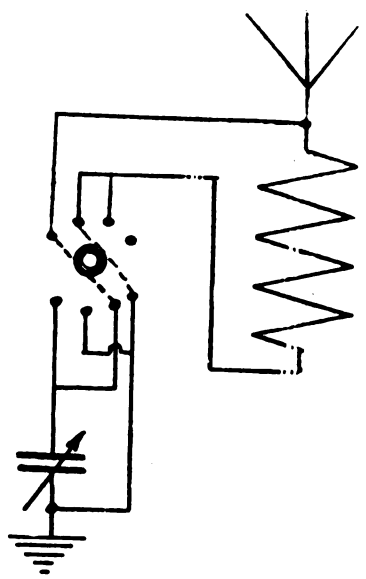

Diagram illustrating the connections on a series-parallel switch in the primary circuit of a receiving set.

circuit of a set.—Adolph Finender, 23 Vine St., Philadelphia, Pa.

The hook-up you desire is given herewith.

* * *

Are the French detector and amplifier tubes any better than the 216A, Meyers and VT 1 and 2 in the "super" circuit?—Wade E. Marshall (no address).

We do not compare the relative advantages of apparatus in this column. However, you will make no mistake in using American apparatus.

* * *

Enclosed find a drawing of the location of my antenna with reference to high tension lines, two branches of the Long Island railroad and power house. I get a continual hum, like the hum of a generator. Can you suggest any way to eliminate it?—L. E. Lowey, c/o New York Telephone Co., New Your City.

From your diagram you seem to be surrounded on three sides by power lines and leads from the power house. We cannot suggest any method outside of using a filter circuit such as described in Radio World for April 28, 1923, by C. White, or hooking-up a filter circuit such as described in Radio World for January 20, 1923, page 20, in answer to a question much the same as yours. You are in a very difficult position as regards clear reception, being surrounded in such a manner by power lines.

Some Real DX Records You Can Shoot At

Captain Halsey Reports 59,190 Miles in 12 Hours 30 Minutes

From Captain J. H. Halsey, S. S. "El Cid," Southern Pacific Steamship Lines, Pier 40, N. R., N. Y. C.

NOTING some DX Nite Owls' records in your interesting journal I decided to send mine in. I keep a log of each station, as well as what they are sending; how I received it and the exact place I am at the time, as I change my position every day, running between New York and Galveston, Texas. In all I have logged 164 different stations since January 4, 1923. I am using a variation of the Flewelling circuit, with two steps, but never use second step, as ship's vibration causes distortion and rattling.

The following stations were heard on March 23-24-26 in 3 hours 30 minutes time: WKAQ, Porto Rico, 1,350 miles; WOR, Bamberger's, 1,250 miles; WGY, Schenectady, 1,350 miles; KDKA, Pittsburgh, 1,050 miles; WEAF, New York Telephone, 1,264 miles; WDAF, Kansas City Star, 855 miles; WBAP, Fort Worth Star-Telegram, 615 miles; KSD, St. Louis Post-Despatch, 775 miles; WDAO, Dallas, Texas, 580 miles; WHB, Kansas City (Sweeny's Auto School), 855 miles; WBZ, Springfield, Mass., 1,375 miles; WOS, Jefferson City, Mo., 780 miles; WEAY, Iris Theatre, Houston, Texas, 575 miles; WWJ, Detroit News, Detroit, 1,090 miles; WHAS, Louisville, Ky., 760 miles; WSY, Birmingham, Ala., 420 miles; WDAJ, College Park, Ga., 500 miles; WFAA, Dallas, Texas, 580 miles; WPA, Fort Worth Record, 615 miles. Total 16,429 miles.

(March 24—Off Tortugas, Fla., 4 hours 20 minutes.)

Belge, Honduras, Tropical. Radio Corp., 600 miles; WDAJ, College Park, Ga., 625 miles; WGM, Atlanta Constitution, Atlanta, Ga., 620 miles; WHAB, Galveston, Texas, 700 miles; WJZ, Waldorf-Astoria, New York, 1,250 miles; KSD, St. Louis Post-Despatch, 1,100 miles; WOC, Davenport, Ia., 1,250 miles; WBAP, Fort Worth Star, 1,035 miles; KFI, Los Angeles, Cal., 2,295 miles; WFAA, Dallas, Texas, 1,000 miles; WIP, Philadelphia, Pa., 1,175 miles; KWH, Los Angeles, Cal., 2,295 miles; WSB, Atlanta Journal, Atlanta, Ga., 620 miles; WDAF, Kansas City, Mo., 1,250 miles; telephone conversation between Catalina Island and San Pedro, 2,275 miles; WHB, Kansas City, Mo., 1,250 miles; WEAF, New York, 1,250 miles; WCAY, Wilwaukee, Wis., 1,375 miles; WHA, Madison, Wis., 1,385 miles; WDAL, Jacksonville, Fla., 425 miles. Total, 25,080 miles.

(March 26—200' Southwest of Cape Hatteras, 4 hours 40 minutes.)

WEAF, New York, 625 miles; WOR, Bamberger's, 616 miles; WGY, Schenectady, 760 miles; WBAV, Columbus, Ohio, 575 miles; WHAZ, Troy, N. Y., 760 miles; WDAV, Muskogee, Okla., 1,050 miles; WSY, Birmingham, Ala., 575 miles; WOS, Jefferson City, Mo., 975 miles; WOO, Philadelphia, Pa., 550 miles; WDAA, Nashville, Tenn., 600 miles; WLW, Cincinnati, Ohio, 650 miles; WWX, Washington, D. C., 415 miles; WJAZ, Chicago, Ill., 850 miles; KDKA, Pittsburgh, Pa., 550 miles; WJZ, New York, 625 miles; WGM, Atlanta, Ga., 390 miles; WDAP, Chicago, Ill., 850 miles; WOC, Davenport, Ia., 970 miles; WDAJ, College Park, Ga., 400 miles; WDAF, Kansas City, Mo., 1,075 miles; WDDR, Philadelphia, Pa., 550 miles; WBZ, Springfield, Mass., 710 miles; KSD, St. Louis Post-Despatch, 820 miles; WBAP, Fort Worth Star, 1,250 miles; WSB, Atlanta, Ga., 390 miles. Total, 17,681 miles. Grand Total, 59,190 miles in 12 hours 30 minutes.

My aerial is one single wire between trucks of each mast, about 300 feet long, entirely separate from ship's aerial.

THE editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

An Old Friend Came Out of His Shell

From J. A. Gillem, Piqua, Ohio.

I HAVE been a reader of RADIO WORLD since your first issue; and, being interested in the DX Nite Owls' page, I thought I would send in my record for three nights.

Using a W. T. No. 501 tube I duplicated eight stations on March 4, and, on March 10, all the above named stations, adding 9XW. I am using a scientific tuner, 23-plate variable condenser, GA grid condenser and a W-D 11 tube, 45 volts on the plate and 1½ volts filament. The tuner is a home-constructed one; the signals are loud, and I am using one tube. I also have a variocoupler instead of the tuner, single-circuit regenerative. It is mounted on the same panel. Brandes superior phones are used. My aerial is 95 feet long, 25 feet high at free end, and 20 feet at the lead-in.

All 'Board! Chicago and All Points West! 'Board!

From Henry A. Brown, 2768 Delaware Ave., Buffalo, N. Y.

In the March 17th issue of RADIO WORLD my attention was directed to Mr. Gordon's hook-up. It has been my intention to write you regarding my results obtained with this little wonder, but have been waiting till California was heard! (from Buffalo, N. Y.). The nearest approach is Butte, Mont. The directions were copied as to panel, etc., but a separate 3-plate vernier was inserted under the condenser, moving that instrument up slightly. A variable grid leak and condenser (Freshman) was also used to good advantage. Not having a W-D 11 I used a U. V. 200.

The first station in was Kansas City, WHB, good and loud. I must admit that I was skeptical, having tried many hook-ups that were supposed to "fill the room laying the phones on the table" or "blowing hats off." You know what I mean. I wish to add my praise and thanks for your contribution to us poor dubs on the side lines like myself who do not know anything about this game until the other fellow tells us. Attached you will find a list of stations heard—by that I mean, *at least one piece clear* and not just sign offs—not having a map handy I do not know what mileage this represents but is a good record for 5 evenings' work.

I live one mile from WGR, Fed. Tel. & Tel., and can tune them out at will. One evening Toronto, Davenport, Philadelphia, Newark, Springfield, Mass., and New York City came in. Two pairs of phones are used, and a friend of mine witnessed the above. I can't tell you exactly what he said, but suffice to say it was very expressive.

WGF—Des Moines, Ia.
WGY—Schenectady, N. Y.

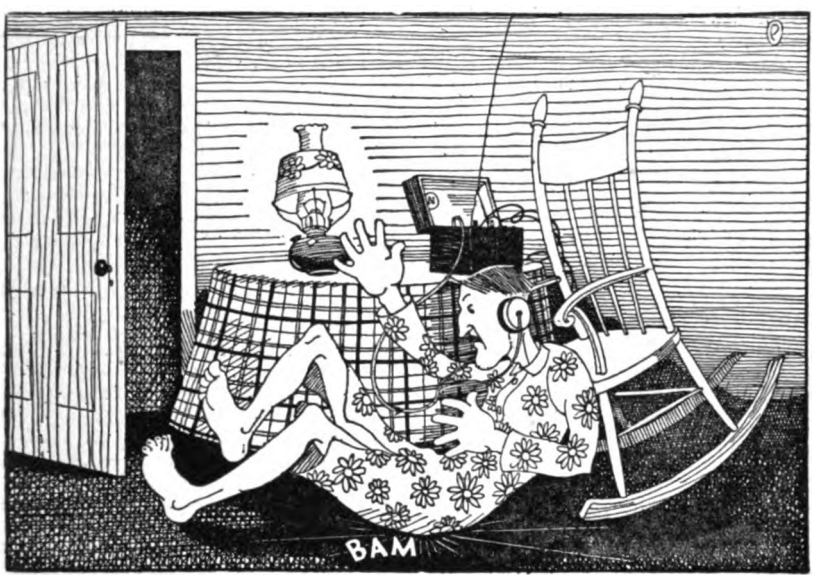
Broadcast Bill's Radiolays

By William E. Douglass

YOU know, the other night I simply couldn't go to sleep an' gosh I tried most every way. I even counted sheep. An' when I passed a thousand they kept jumpin' just the same. Those last three cups of coffee must uv been what wuz to blame. So gently I crept out of bed as quiet as could be n' went down stairs to smoke an' read till maybe two or three, at which time ol' man Morpheus might not be quite so shy. I'd heard of others tryin' it an' 'lowed 'twuz worth a try. I pulled a chair up by the fire but 'fore I lit the light thinks I, "Some station's sending even at this time of night." So you might say suitin' action to the word I got my set an' I clamped those rubber earmuffs on to see what I could get. I listened to an orchestra in Dallas for awhile an' say it wuz a dandy playin' music just my style. I could hardly keep my feet still when they played "I'm All Alone" an' that chap that played the saxophone sure got a wicked tone. Well, almost without thinkin' 'fore I knew what I wuz sayin' I yells "give us one more encore" an' the boys kept right on playin'. 'Course I don't suppose they heard me but one party did I know an' I soon received a message which wuz not by radio. There wuz Min up on the landin' with her night cap on her head an' her message wuz as follows, "You march right up here to bed." "I'll be with you in a minute, dear. Did I disturb your rest?" I answered her real gentle an' just then frum way out west, I picked up another station which was sendin' out a speech on the Famous Men of Russia, an' What They Have Tried to Teach. I'll admit he knew his subject but the next thing that I knew I wuz travelin' in an aeroplane across an ocean blue. As I looked off in the distance I could see a stretch of sand an' I figgered that had ought to make a dandy place to land. All at once I started fallin', droppin' straight down through the air. When I hit it was surprisin' I had fell out of my chair.

(Copyright, 1923, Westinghouse Electric & Manufacturing Company.)



"When I hit it was surprisin'—I had fell out of my chair."

Radio Successfully Penetrates Mine Shaft

AN interesting and highly successful experiment, recently carried out by the members of the Radio and Research Club of the Springfield, Ill., High School, was radio communication between members of the club located in a mine and other members above, at various places around the city.

It has always been a moot question in the minds of radio experts whether successful communication could be carried on between men far below the earth and others at a distance on the surface. The members of the club went down 250 feet with portable apparatus and, under the leadership of A. B. McCall, the faculty adviser of the club, started in to call the world above. The excited listeners at the top of the shaft continued to communicate with them until notice came that another member, located at his home in Springfield, had also heard and answered the signals.

Mine officials from all over the country are interested in the outcome of the experiment because of the fact that it will prove invaluable in mine rescue work in aiding entrapped miners. Rescue crews will be able to keep in constant touch with one another and the surface through the aid of simple and portable apparatus.

Radio Corporation Orders Employees to Become Naturalized Citizens

GEN. J. G. HARBORD, president of the Radio Corporation of America, New York City, has issued an order that all unnaturalized employees of the company must become American citizens. Of the 1,100 employees it is said that only 76 are aliens and that these are nearly all Canadians.

"It is only reasonable," Gen. Harbord is quoted as saying, "that those who are enjoying the privileges and advantages of inhabitants of this country should assume the responsibilities of citizenship. Our charter requires that all elective officers be American citizens, and we are extending this requirement to include all our organization. Any who do not want to be naturalized are at liberty to leave."

Why Magnavox *is* the Reproducer Supreme

OFFICIAL tests with the oscillograph prove that the Magnavox electro-dynamic receiver reproduces incoming wave forms with maximum accuracy.

The Magnavox can be used with any receiving set—the better the set, the more Magnavox can do for you.

When you purchase a Magnavox you possess an instrument of the very highest quality and efficiency.

R2 Magnavox Radio with 18-inch horn
(as illustrated)

This instrument is intended for those who wish the utmost in amplifying power; for clubs, hotels, dance halls, large audiences, etc. It requires only .6 of an ampere for the field. Price, $60.00

R3 Magnavox Radio with 14-inch horn

The ideal instrument for use in homes, offices, amateur stations, etc. Same in principle and construction as Type R2. Price, $35.00

Model C Magnavox Power Amplifier

For use with the Magnavox Radio and insures getting the largest possible power input.

2-stage, $55.00
3-stage, $75.00

Magnavox products can be had of good dealers everywhere.

Duke of York Gets an American Radio Set

A LETTER recently received from a large manufacturer of radio goods—The Eagle Radio Company, 210 Central Avenue, Newark, N. J.—shows how completely American radio manufacturers have captured the field. The letter states in part:

"It might interest the readers of your magazine as a news item to note that the following Associated Press report was received on April 26, the date of the Duke of York's wedding, relative to the Eagle Portabloop receiver set:

"'One of the most unique and most appreciated gifts received by the Duke from the United States is a powerful receiving set built upon a mahogany tea wagon.'"

It is the belief that this radio receiver was the only one received by the Duke as a wedding present. It was purchased from one of the Eagle company's New York City dealers—Kellogg & Bertine, 631 Madison Avenue.

A High Grade, Low Price Grid Leak

A WELCOME accessory to the field of radio parts, and one that will be duly appreciated by fans who construct their own sets, is a cheap and extremely well made grid leak manufactured by the Airex Company, 237 Centre Street, New York City. In appearance the leak somewhat resembles an overgrown paper condenser, with a small scale and pointer on it. It is constructed of thin fibre, and is extremely reliable over a range of from 0-10 megs. which gives enough latitude for the most finicky builder. It is neatly made, and, as there are no composition parts to chip and break, and is extremely thin, it should meet with a great reception by the fans. It sells for 25 cents, which is a revelation in these days of high prices.

An Efficient Portable Regenerative Receiver

CHARLES A. PEZET, 46 West 65th Street, New York City, has perfected a portable receiving set that actually deserves the name. The dimensions of the case are only 12¼ by 9½ by 4¼ inches, and the total weight is only five pounds.

But its portability is matched by the efficiency of the set. Mr. Pezet has based his circuit on the Armstrong triple circuit, using three Litz wound spiderwebs as tuning inductances for primary, secondary and tickler circuits. The set can be worked either on a WD-11 or UV-199 tube. A special feature of the set is an extra connection, with which it is possible to operate it with a ground alone or an antenna alone. It is claimed by the builder that this set has brought in stations hundreds of miles away and has tuned out local interference that has bothered larger, more bulky sets.

Federal Tel. & Tel. Co.'s Guarantee and What Is Back of It

THE Federal Telephone & Telegraph Company, Buffalo, N. Y., one of the best known and staunchest manufacturers in the telephone and radio industries, recently adopted a guarantee, which is printed on a tag and attached to each of its products. It reads as follows:

"We hereby guarantee Federal Standard Radio Products to be free from all mechanical and electrical defects, and to function properly when installed in accordance with our authorized directions, and we agree to replace, at our expense, any unit or part which may prove defective."

As any guarantee is dependent upon the financial ability of the maker to live up to it, the following statement of the assets and liabilities of the Federal company should be of convincing interest:

BALANCE SHEET, JANUARY 1, 1923.

Assets

Cash	$124,259.98
Notes and Accounts Receivable	749,868.96
Real Estate and Inventory.....	2,439,442.77
Investments, Stocks and Bonds at par	7,272,433.71
Franchises, Patents, etc.....	523,761.35
Prepayments	124,739.07
	$11,234,505.84

Liabilities

Stock Issued	$7,282,750.00
Accounts Payable	73,925.98
Notes Payable	2,728,293.37
Accrued Accounts	27,130.39
Funded Debt	391,700.00
Surplus	730,706.10
	$11,234,505.84

RADIO WORLD congratulates the Federal company on this significant and forward step, which undoubtedly will be followed by others and do much to standardize radio equipment and stabilize merchandising conditions throughout the entire radio industry.

New Radio and Electric Firms

Electrical Home Needs Co., Cleveland, Ohio; L. P. Kearns, R. G. Latom, B. D. Zieve, A. Cline and F. P. Chapin.

Bat-Electric Service Co., 619 State St., Watertown, N. Y.

E. H. Freeman Electric Co. has removed to 10 Prince St., Trenton, N. J.

Electrical Supply & Equipment Co. will occupy a new four-story building at 278 Broadway, Albany, N. Y.

Service Electric Co. has removed to 116 Washington St., Binghamton, N. Y.

Reeservice Shop is the new name of Reeservice Music Shop, 108 Main St., Cambridge City, Ind. Increased radio business is reported.

Southern New York Electrical Supply Corp., 78 State St., Binghamton, N. Y. W. H. Hecox, E. C. Wehle and H. A. Yetter.

Directors of Boys' and Girls' Summer Camps

FOLLOWING is a list of names and addresses of directors of boys' and girls' summer camps, each of whom should be a potential purchaser of radio sets for camp and vacation use. Additions to the list will be published in succeeding issues of RADIO WORLD:

R. C. Frank, 620 West 122d St., New York.
G. R. Frank, 192 Parkwood Ave., Columbus, Ohio.
Louis M. Fleisher, 1218 Walnut St., Philadelphia, Pa.
Samuel G. Friedman, 1422 North 16th St., Philadelphia, Pa.
Edward A. Carlson, 118 Coulter Ave., Ardmore, Pa.
Ralph I. Underhill, Scarsdale, N. Y.
Harvey C. Went, 1083 Noble Ave., Bridgeport, Conn.
Irving G. McColl, Hotel McAlpin, New York.
Jacob M. Ross, 575 West 172d St., New York.
Ephraim Weinstein, 455 Ft. Washington Ave., New York.
George A. Kohut., Ph.D., 220 West 87th St., New York.
Harry J. Kugel, Kohut School for Boys, Harrison, N. Y.
Edwin V. Spooner, Exeter, N. H.
Frank E. Poland, 22 Oak Terrace, Malden, Mass.
W. S. Cowing, 21 Carver Rd., Newton Highlands, Mass.
Henry Richards, Gardiner, Me.
Guy W. Chipman, 15 Clark St., Brooklyn, N. Y.
Mrs. E. D. Baylis, 1021 Ocean Ave., Brooklyn, N. Y.
Andrew I. Albert, 1728 Crotona Park East, New York.
A. A. Jameson, 615 Chamber Commerce Bldg., Atlanta, Ga.
Edward M. Healy, 227 Roseville Ave., Newark, N. J.
C. E. Allen, 19 Ricker Rd., Newton, Mass.
A. R. Webster, 1325 Cypress St., Cincinnati, Ohio.
Joseph I. Gorfinkle, Mount Vernon, N. Y.
C. E. Allen, 19 Ricker Rd., Newton, Mass.
Joseph C. Saltman, 1454 Grand Concourse, New York.
Mr. and Mrs. R. L. Marsans, 519 Second St., Brooklyn, N. Y.
A. E. Hamilton, Raymond, Me.
Mrs. F. T. Burdett, 239 Park Ave., East Orange, N. J.
Miss Mary E. Richardson, 69 Woodmont Ave., Mittineague, Mass.
Miss Margaret H. Schmidt, 128 Leicester St., Detroit, Mich.
Miss Edith A. Steere, Packard Rd., Ann Arbor, Mich.
Miss Edith P. Holt, 39 Fitch Pl. S. E., Grand Rapids, Mich.
Miss Winifred Schureman, 1780 Lyndale Ave., South Minneapolis, Minn.
Dr. and Mrs. J. Grant Quinby, Lakeport, N. H.
Mrs. Blanche Carstens, 523 Washington St., Brookline, Mass.
Mrs. N. S. Winchester, 31 East Haverhill St., Lawrence, Mass.
Miss A. R. Hazelton, 14 Billingham St., Somerville, Mass.
Miss Alice Hazelton, 14 Billingham St., Somerville, Mass.
Dr. Ann Tomkins Gibson, 6323 Lancaster Ave., Philadelphia, Pa.
Calvin Sargent, New London, N. H.
Miss Mary H. MacCracken, Mount Vernon Seminary, Washington, D. C.
Julia E. Lancaster, Newton Center, Mass.
Miss Lena Seitlen, 572 Blue Hill Ave., Roxbury, Mass.
Miss Rachel Rosnosky, 29 Richfield St., Dorchester, Mass.
Mrs. Morris Klein, 617 West 141st St., New York.
Mrs. S. Evannah Price, 40 High St., Springfield, Mass.
George W. Orton, 39 South 10th St., Philadelphia, Pa.
Ernest P. Roberts, 55 Hanson Pl., Brooklyn, N. Y.
B. B. Girden, 3805 Review Pl., New York.
C. Ward Crampton, M.D., 18 East 78th St., New York.
Wallace Greene Arnold, 81 Jane St., New York.
Robert Tindale, 31 East 71st St., New York.
Miss Esther Hamburger, 250 West 103d St., New York.
Miss Mildred Hamburger, 250 West 103d St., New York.
Miss Fanny G. Crenshaw, 919 Franklin St., Richmond, Va.
Mrs. N. B. Adams, 509 West 121st St., New York.
Mrs. Fannie L. Bernstein, 385 Ft. Washington Ave., New York.
Jacob Heniger, 230 West End Ave., New York.
Miss Effie Berdann, Hotel Wolcott, New York.
Miss Dora Weil, 2020 Eutaw Pl., Baltimore, Md.
Mrs. C. P. Towne, Woodland Park, Auburndale, Mass.
Mrs. M. Thorner, 2672 Boulevard, Jersey City, N. J.
Miss Emily H. Welch, 476 Norwood Ave., Buffalo, N. Y.
Robert A. Patterson, Kingswood School, Hartford, Conn.
D. H. Markham, University of Arkansas, Fayetteville, Ark.
Joy Pratt Markham, Fayetteville, Ark.
E. C. Offinger, 14708 Shaw Ave., East Cleveland, Ohio.
Ralph S. Pitts, 130 Grant St., Denver, Colo.
Tedford Cann, 2259 Loring Place, New York.
Emil Von Elling, New York University.
John H. Bruns, 153 E. 86th St., New York.
Frank T. Essig, 5 West 125th St., New York.
Miss Blanche Hirsch, 5 West 91st St., New York.
Miss Clara Altschul, 5 West 91st St., New York.
Miss Ethel L. Sargent, 58 Glenville Ave., Allston, Mass.
Miss Harriet M. Balcom, 58 Glenville Ave., Allston, Mass.
Miss Rose Sommerfeld, 225 East 63d St., New York.
Mrs. Bella Hirsch, 309 West 86th St., New York.
Ethel B. Mayall, Princeton, N. J.
Miss Alice H. Belding, Randolph-Macon Coll., Lynchburg, Va.
Wm. Gould Vinal, Rhode Island College Education, Providence.
Miss Beatrice A. Hunt, Holbrook, Mass.
Mr. and Mrs. I. Spectorsky, 232 West 112th St., New York.
Mrs. E. A. W. Hammatt, South Orleans, Mass.
Samuel Schlosberg, 11 Lathers Pl., New Rochelle, N. Y.
Albert Loewinthan, 227 Audubon Ave., New York.
Miss Mary D. Snyder, 362 S. Broadway, Lexington, Ky.
Miss Sara G. Blanding, 548 Central Ave., Lexington, Ky.
Mrs. Clara F. Liebman, 409 Edgecombe Ave., New New York.
Dr. Emma G. Wood, Box 416, Maplewood, N. J.

(To be continued)

U. S. S. "Guide" Wants a Chief Radio Operator

EDITOR, RADIO WORLD: The U. S. Coast and Geodetic Survey steamer "Guide" is outfitting and assembling a crew at the present time, and we are desirous of enlisting a Chief Radio Operator. The pay of this rating is $90 per month. The rating is equal to a C. P. O. in the United States Navy, but the man is not an officer. The man must enlist for a period of one year. The ship will probably go to the west coast of the United States in the late summer, and work on that coast thereafter.

We are desirous of getting a man who has had navy experience, preferably a man who was on minesweepers, as this vessel has the minesweeper radio equipment.

If you know of any men who would be interested in this position please refer them to me at the address below, and it will be greatly appreciated.

Respectfully,
K. T. ADAMS,
Executive Officer, U. S. S. "Guide."
West New Brighton, N. Y.

Wireless Expert's Kidnapped Son Sought by Radio

VERNER ALEXANDERSON, the six-year-old son of E. F. W. Alexanderson, chief engineer of the Radio Corporation of America, was kidnapped from his home at Schenectady, N. Y., on April 30.

News of the crime was almost immediately broadcast from Station WGY of the General Electric Company at Schenectady. Since then WJZ, the Westinghouse station at Newark, N. J., has also broadcast news of the child's disappearance. Both stations, as well as several others, have sent out detailed descriptions of the boy, and these have been picked up by many amateurs and police department officials.

Mr. Alexanderson has offered a reward of $1,000 for any clue to finding his son, and the city of Schenectady has offered another reward of equal amount.

When he was kidnapped Verner was playing in the yard of his home with his two sisters when a stranger approached. After engaging the children in conversation he offered to get a pair of rabbits for the boy, and sent the sisters for a box in which to put them. When the little girls returned the boy and the strange man had disappeared.

A number of fruitless clues have been followed. The broadcasting has been repeated several times since the kidnapping. The child was found near Theresa, N. Y., on May 3.

"MANY INQUIRIES—LARGE SALES—CONTINUE THE AD!" SAYS RADIO WORLD ADVERTISER

Frederick H. Pruden, Incorporated

Manufacturers Representatives Electrical and Radio Apparatus
Lerner Building, Journal Square, Jersey City, N. J.

Editor, Radio World:—We are very pleased to inform you that our advertising through your medium has resulted in the largest number of inquiries received from all other advertising mediums.

These inquiries have resulted in a large number of sales. They have come to us through your paper from India, France, Cuba and Canada. No one knows where the next one will come from, perhaps from Japan or China.

It is our belief that your paper, although a comparatively new one in the radio field, compares favorably, if it does not excel, some of the older publications. It is our intention to continue advertising in every issue.

Yours very truly,
Frederick H. Pruden, Incorporated

The Associated Radio Industries of St. Louis

AN association of radio dealers, jobbers, manufacturers and manufacturers agents has been formed in St. Louis, Mo., for the purpose of co-operation and good fellowship. The officers are: President, C. H. Wilson, Manhattan Electric Supply Co.; vice-president, W. E. Fuetterer, Fuetterer Battery Service Co.; Secretary, W. E. Kuhn, Security Radio and Auto Supply Co.; treasurer, R. W. Lawrence, Lawrence Radio Corporation. The directors are: W. Saltmarsh, The McGraw Co.; H. B. Engel, Sobeig-Engel Co.; C. Brunswick, Brunswick Electric Co.

The association has adopted this slogan: "Buy Satisfactory Radio from Dependable Dealers." Members will be supplied with a large card bearing the emblem and slogan to be placed in their stores and will run co-operative advertising in the local newspapers continuously. It is also the intention of the association to take charge of all future radio shows. The cost of membership is $10 initiation and $10 yearly dues.

Partial Program of WGY

THE Chamber of Commerce of Watervliet, N. Y., will provide the concert for Thursday night, May 10, broadcast from WGY, the General Electric Company's station at Schenectady, N. Y. The program will include orchestral and vocal quartet selections as well as solos, and Colonel W. I. Westervelt, U. S. Commandant of the Watervliet Arsenal, will talk on "The U. S. Army Gun Plant." A special feature will be a chime selection by Ernest A. Meneely. The chime set to be used is the only one of its kind and was recently turned out by the Meneely Bell Foundry.

During the early concert Friday night, May 11, J. C. Warner will give a talk on the UV-201-A and UV-199 tubes. At 10:30 o'clock Friday night, the WGY Players will present Langdon McCormick's play, "The Storm." The WGY Players will be assisted by Harry Hollingsworth and Nan Crawford, Van Curler Players.

Saturday evening a program of dance music will be broadcast from Cain's Dance Castle.

Why His Set Didn't Receive

HE was a bumptious radio fan. He could pick up St. Louis, Chicago, San Francisco, according to the New York "Sun." He was never tired of telling particularly the meek little man who owned a cheap amateur set what wonderful times he had listening in. "You ought to get a real outfit," was his stock expression.

One night the meek little man knocked on the door of the bumptious one. "I can't seem to pick up the Blank Orchestra," he explained apologetically. "I'm wondering if it's static or something like that."

"Nothing of the kind. It's just your bum outfit. Come on in and we'll pick it up on mine."

But the bumptious one didn't have any better luck than his humbler neighbor. He grew wrath. "This set's no good. I'll get another. I'll throw this one out!"

"Would—would you sell it to me?" asked the meek one timidly.

"Sell it to you! Take it!"

The meek little man departed rejoicing in his good luck.

And now the bumptious one is off radio for life. His outfit was perfectly good; there was no atmospheric disturbance; the Blank Orchestra was on strike that particular night.

Fifty-two issues for $6.00. Subscription Department, RADIO WORLD, 1493 Broadway, New York City.

Good Bye Aerials!
So Long Static!

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

What Makes an Advertisement Pay?

There is an interesting editorial in the Advertising Club "News" this week telling how the same mail order advertiser had two advertisements prepared by two different copy writers.

Each adv. was of the same size, in the same publication, advertising the same article at the same price, and so "keyed" that an exact record could be kept of the returns from each.

One advertisement brought inquiries at $1.34 each and produced business amounting to $742. The other adv. brought inquiries at 18c. each and produced business amounting to $4,452.

See the letter of Frederick H. Pruden in another column, and note the fine results RADIO WORLD brought him. It will bring any other manufacturer or distributor equally good results—if the advertising copy is equally good.

RADIO WORLD's copy chief has had twenty years' experience. We are in intimate touch with our readers, know their buying problems and interest, receiving as we do hundreds of letters and inquiries from them daily from every part of the country. We are at your service. Address Advertising Copy Chief, RADIO WORLD, 1493 Broadway, New York.

Subscribe for RADIO WORLD, $6.00 a year, $3.00 six months, $1.50 three months.

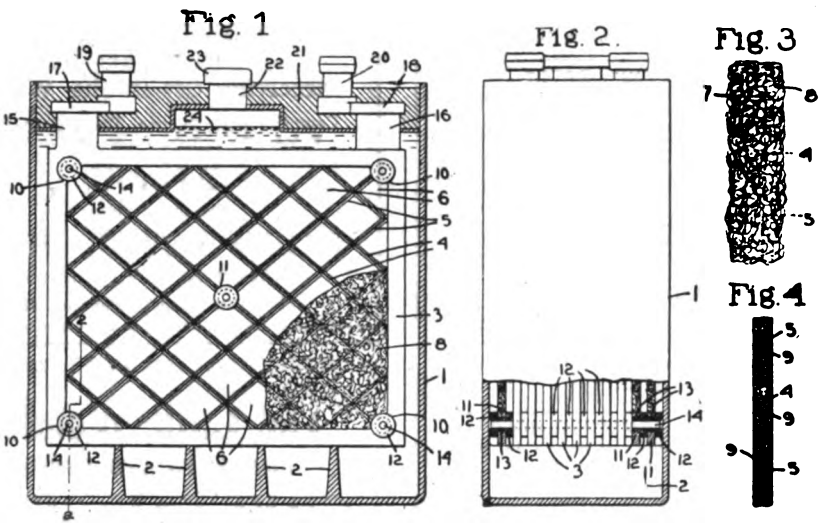
Storage Battery and Process

No. 1,450,533: Patented April 3, 1923. Patentee: Albert H. Williams, Worcester, Mass.

THIS invention relates to improvements in storage batteries and the process of producing the same and the general object thereof is to provide a storage battery which will have a greater efficiency and a longer life than batteries heretofore constructed and which can be produced at a much less cost, and in a shorter time. More specifically the object of the invention consists in the production of a storage battery comprising plates in which the active material is of greater strength and purity and of increased and uniform porosity which will enable a better circulation of the electrolyte and in which the conductivity of the active element will be increased by the perfect electric contact between the particles of the active material, so that the electrical resistance will be reduced and in which, by reason of the purity and porosity of the active material, substantially no local electric action will take place and polarization during a heavy rate of charge or discharge will be substantially eliminated. A further object of the invention is to produce plates for a storage battery which will not warp or buckle and which will be of such a character that the breaking away of the active element during charging and discharging will be substantially eliminated. A further object of the invention is to provide an electric battery of a character which will not require the positioning of separator plates between the positive and negative plates of the battery, whereby the resistance of the usual separator plates to the passage of the electric current through the electrolyte will be eliminated. A further object of the invention is to provide a storage battery in which the negative and the positive plates as initially constructed will be composed of a core or grid having pure sponge lead integrally attached or welded thereto. Another object of the invention consists in treating the plates in such a manner during their production that the necessity for the long period of charging usually required in the production of storage batteries will be rendered unnecessary and a completely charged storage battery produced within the period of less than an hour, whereas in batteries as hereto fore produced the construction and charging of the batteries usually requires several days.

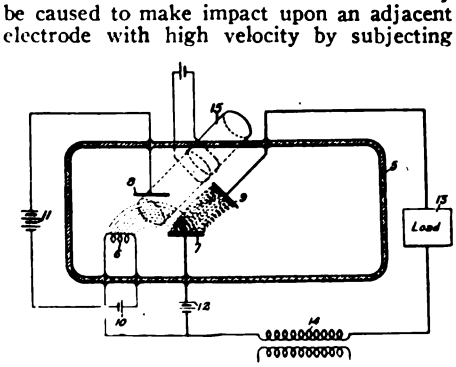


Albert G. Williams' new method of filling the plates in a storage battery with sponge lead, exposing a greater surface to the electrolyte.

Hot-Cathode Tube

No. 1,450,265: Patented April 3, 1923. Patentee: Joseph Slepian, Wilkinsburg, Pa.

THIS invention relates to hot-cathode apparatus, such as is used for rectification and in detector-bulb work and it has for its object to provide apparatus of the character designated that shall embody means for providing a strong and effective electron emission. The accompanying drawing is a diagrammatic view of an electron tube, together with associated supply and auxiliary circuits, illustrating one application of the invention. In the construction and operation of electron tubes, it has been usual to employ incandescent filaments as electron sources, these filaments being maintained at incandescence by the passage of heating current there through. The use of a filament of sufficient size and temperature to produce the large electron streams required in certain forms of apparatus engenders a relatively large amount of heat that must be dissipated and, furthermore, the filament is subject to rapid deterioration because of the high temperature at which it must be run, thus limiting the useful life of the apparatus. A relatively small incandescing filament may be operated at moderate temperatures to produce a small number of electrons and these electrons may be caused to make impact upon an adjacent electrode with high velocity by subjecting them to the influence of a high-voltage electrostatic field. As a result, there is produced a profuse emission of electrons from the adjacent electrode by the joint action of reflection and of secondary emission, it being well known that the impact of a high-velocity electron upon another body may set free a large number of low-velocity electrons therefrom. The adjacent electrode, which is thus caused to be the seat of a profuse electron emission, may now be employed as a cathode in an auxiliary circuit, and a relatively large amount of current may be offered passage because of the large number of electrons available. If desired, the above process may be repeated, and the electrons set free from the adjacent electrode be caused to make impact upon still another electrode, setting free a still larger number of electrons therefrom, and this process may be continued indefinitely. A convenient method of manipulating the electron streams, in apparatus of this type, is by means of magnetic fields.

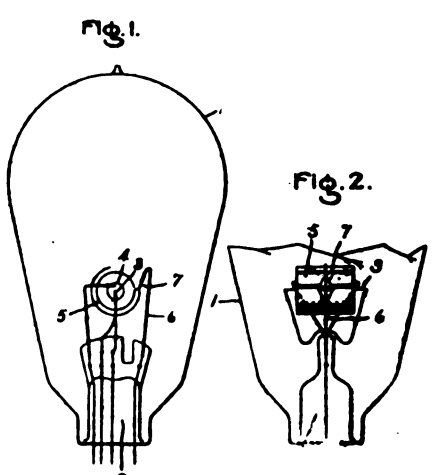


New method of sustaining electronic flow in a vacuum tube.

Vacuum Electric Discharge Device

No. 1,450,413: Patented April 3, 1923. Patentees: Herbert W. Edmundson and William T. Munro, Rugby, England.

THIS invention relates to vacuum electric discharge devices of the kind known as valves, rectifiers or the like such as are used in wireless telegraphy and for other purposes in which a heated cathode is employed. The object of the invention is to provide an improved discharge device in which the destructive effects resulting from the heat produced in the anode by the bombardment of the electrons from the cathode are eliminated as far as possible. According to the invention a shield preferably of metal is mounted within the device in such a position as to cut off the heat radiated from the anode during operation of the device. This shield may be of different shape according to the construction of the discharge device, and is separated from the anode so that the vacuous space between it and the latter serves to prevent it from becoming heated to any considerable extent. In applying the invention to a form of valve in which the cathode is located within a cylindrical anode, the whole being mounted on a glass stem within an evacuated bulb, the stem carrying the leading-in conductors for the device, the shield may be in the form of a cylinder of thin sheet metal almost completely, or completely, surrounding the anode or interposed between the anode and stem in any convenient way so as to prevent the stem through which the leading-in wires pass from being heated by direct radiation from the surface of the anode. As a result the heat radiated from the anode will be prevented from injuriously affecting the seal.



New constructional idea applied to a vacuum in order to prevent deterioration of elements through heat radiation from filament.

Radio Telephony Rapidly Growing in Chile

IN Santiago, Valparaiso, and several other smaller Chilean cities, interest in radio telephony is growing steadily, and its fuller development only awaits the establishment of a broadcasting station within the country, such as those now in operation on the east coast of South America, says Assistant Trade Commissioner W. E. Embry in a report to the Department of Commerce. It is reported that the broadcasting stations recently erected in Buenos Aires, Montevideo, and Rio de Janeiro have given very satisfactory results, and large numbers of amateur receiving sets have been sold in these countries. This is especially true of the Argentine, where conditions for broadcasting programs are almost ideal, as the land generally is flat and radio transmission carries all over the River Plate district, Uruguay, and into southern Brazil on the north and as far as the Andes on the east. For this reason the sale of radio equipment has met with the greatest success in this country, and it is now estimated that there are approximately 25,000 sets in the Argentine Republic in comparison with approximately 100 less than one year ago.

American radio equipment, up to the present time, has been given preference. This is especially true of Chilean orders, as practically all equipment now in use in Chile is of American origin. Four or five concerns in Santiago deal in this class of goods, and a similar number handle radio apparatus in Valparaiso. Estimates of the number of sets throughout Chile vary between 100 and 500.

The Chile Radio Corporation, a local Chilean concern, with offices on the top floor of the highest office building in Santiago, has a very good amateur broadcasting station with one-kilowatt power, and programs consisting mainly of music are being offered from time to time. Outlying cities within a radius of 300 miles report that the concerts are heard very distinctly under normal weather conditions.

Another smaller broadcasting station has been maintained in Providencia for the past three or four months by a local amateur radio enthusiast, and programs consisting of phonograph records have been broadcast successfully. Providencia is an outlying suburb of Santiago. The broadcasting from this station is carried on by an improvised equipment of 20 watts power.

Numerous native Chileans have shown unusual interest in all matters pertaining to radiotelephony and its development. Amateur sets have been constructed and experiments are continually being made by local amateur enthusiasts. It is not unusual for amateurs in Santiago to receive, or rather intercept, messages sent out from stations in Honolulu, France, Japan, the United States, and other distant places. One of the local amateur stations recently heard very distinct messages from Arlington, District of Columbia.

Non-Sectarian Church to Receive Services by Radio

At Wellesley Hills, Mass., a new church will soon be opened which, instead of broadcasting its services, will receive them from other churches or from broadcasting stations by special arrangement. Roger W. Babson, the noted statistician, is the donor of the church, which will be equipped with a radiophone receiving set and loud speaker. Thus the music, sermons, prayers and other features of church ritual will be audible to the congregation. The church will be non-sectarian. On Sundays services will be held for Catholics, Baptists, Congregationalists

PATENTS—SEND DRAWING OR MODEL FOR EXAMINATION AND OPINION. Booklet free. Watson E. Coleman, Patent Lawyer, 624 F Street, Washington, D. C.

ARE YOU IN THE RADIO BUSINESS? If so, drop us a card for price list. If not, let us start you in a good paying business. We furnish everything and have a proposition that meets the needs of 90% of the public. Liberal discounts to agents. Immediate delivery. Write today. THE WILKENDA COMPANY, 500 Fifth Avenue, New York.

BUILDERS AND EXPERIMENTERS. Do you know that the Reflex circuit is one of the most interesting circuits to construct? You can not guess how much fun you are missing if you fail to try out at least one of these circuits. See RADIO WORLD issues of Feb. 24 and March 3. They contain two fine articles by W. S. Thompson, with plenty of new Reflex circuits to experiment with. Don't miss these! 15c. a copy. RADIO WORLD, 1493 Broadway, New York City.

CRAM'S RADIO BROADCASTING MAP of the UNITED STATES & CANADA. Scale 100 miles to the inch. In two colors, size 34x28. Printed on high-grade map paper, up-to-the-minute information, indicating all amateur and standard broadcasting stations, with complete index to stations. 35c postpaid. The Columbia Print, 1493 Broadway, N. Y. C.

TWENTIETH CENTURY BOOK OF RECIPES, FORMULAS AND PROCESSES—Edited by Gardner D. Hiscox. This book of 800 pages is the most complete book of recipes ever published, giving thousands of recipes for the manufacture of valuable articles for every-day use. Hints, helps, practical ideas and secret processes are revealed within its pages. It covers every branch of the useful arts and tells thousands of ways of making money and is just the book everyone should have at his command. The pages are filled with matters of intense interest and immeasurable practical value to the photographer, the perfumer, the painter, the manufacturer of glues, pastes, cements and mucilages, the physician, the druggist, the electrician, the dentist, the engineer, the foundryman, the machinist, the potter, the tanner, the confectioner, the chiropodist, the manufacturer of chemic novelties and toilet preparations, the dyer, the electroplater, the enameler, the engraver, the glass worker, the gold-beater, the watchmaker, the jeweler, the ink manufacturer, the optician, the farmer, the dairyman, the paper maker, the metal worker, the soap maker and the technologist in general. A book to which you may turn with confidence that you will find what you are looking for. A mine of information up-to-date in every respect. Contains an immense number of formulas that everyone ought to have that are not found in any other work. New edition. 807 octavo pages. Cloth binding. Price, $4.00. The Columbia Print, 1493 Broadway, New York City.

RADIO FANS AND PROFESSIONALS—How many of you know the correct CODIFICATION of all characters, punctuations and signs (such as $, %, etc.). We dare say that nine out of ten don't know them correctly! Our instructor who has had 35 years experience, eight years of which were with Uncle Sam as MORSE and RADIO TELEGRAPHER, has just published the first and only CHART known to give fully a true and correct CODIFICATION of ALL characters used in both codes. This CHART is indispensable to all up-to-date beginners and veterans alike. Fifty cents (money order preferred) will bring CHART, also much information extremely interesting to BOYS and GIRLS; because, with this information and a little PEP on your part, you can qualify shortly (as scores of our graduates have done) and secure positions paying $1,500 to $3,000 yearly. (See Civil Service Bulletins 215, 357 and 54.) We are registered with the U. S. C. S. Com. at Washington and can help you. AMERICAN TELEGRAPHIC STUDIO, BOX 793, WORCESTER, MASS.

Directions apply equally to a shop. Sixth edition. COLUMBIA PRINT, 1493 Broadway, N. Y. C. Price, 25 cents.

ELEMENTS OF RADIO TELEPHONY, by Wm. C. Ballard, Jr. A standard book on radio telephony, the work of a recognized authority. Accurate, simple, clear, reliable and strictly up-to-date. For the technical man who wants to post himself on radio and for the radio enthusiast who wants the fundamental principles of radio and their application tersely and entertainingly presented. Price, postpaid, $1.50. The Columbia Print, 1493 Broadway, New York.

MOTOR BOATS AND BOAT MOTORS—By V. W. Pagé and A. C. Leitch. All who are interested in motor boats will find this latest work a most comprehensive treatise on the design, construction, operation and repair of motor boats and their power plants. It is really two complete books in one cover, as it consists of two parts, each complete in itself. Part one deals with THE HULL AND ITS FITTINGS, part two considers THE POWER PLANT AND ITS AUXILIARIES. A valuable feature of this book is the complete set of dimensioned working drawings detailing the construction of five different types of boats ranging from a 16-foot shallow draft, tunnel stern general utility craft to a 25-foot cabin cruiser. It is a comprehensive work of reference for all interested in motor boating in any of its phases. 372 illustrations. 524 pages. New Edition. **Price, $4.00.** THE COLUMBIA PRINT, 1493 Broadway, New York City.

DO YOU WANT TO SAVE MONEY in making your set? Send for the Jan. 27 issue of RADIO WORLD, containing a full-page drawing of how to make filament control rheostats, as well as an easily understandable text, which makes the construction easy. 15c a copy, or start your subscription with this issue. RADIO WORLD, 1493 Broadway, New York.

IF YOU ARE A REGULAR RADIO fan and like to hear the stations in the four corners of the United States come in with a bang, then you will want the Flewelling Circuit. If you do, send 15c for RADIO WORLD, issue of Feb. 24, which contains complete description and directions for the manipulation of the circuit. RADIO WORLD, 1493 Broadway, New York.

EXCHANGE JOLLY, INTERESTING LETTERS through our club. Stamp appreciated. Betty Lee, Inc., 4254 Broadway, New York City

United States Radio Exports During 1922

THE total value of radio apparatus exports from the United States in 1922, as compiled by the Department of Commerce, was $2,897,799, distributed among the various months as follows: January, $9,274; February, $283,950; March, $21,180; April, $116,221; May, $186,525; June, $547,364; July, $385,861; August, $188,670; September, $207,535; October, $564,803; November, $223,180; December, $163,236.

Statistics showing the United States exports of radio apparatus include, of course, material for high-power telegraph stations, several of which are being erected with apparatus shipped during 1922. This accounts for the relatively high percentage exported to Poland, Cuba, Mexico, Japan, Uruguay, and probably, to some extent, Argentina.

Canada ranks with the domestic market on account of the large amount of broadcasting being done and the proximity of its centers of population to stations in the United States. The heavy shipments to Argentina last fall were intended partly for Chile and other neighboring countries, Buenos Aires being used as a distributing point.

It is interesting to note that over 81.5 per cent. of the entire amount exported was shipped to four countries, whose total population (89,141,219) is only a little under 6 per cent. of that of the entire world outside of the United States. The following percentage of the total United States radio apparatus exports in 1922 was taken by the various countries: Canada, 28.2; Argentina, 22.5; Poland and Danzig, 19.8; England, 11; Cuba, 4.1; Mexico, 3; Brazil, 2.6; Japan, 1.4; Uruguay, 1.4; Philippine Island, 1.1; New Zealand, 1, and all other countries, 3.5.

Radio Permeates the Universe

First Yegg—"Say, Bill, I seen a radio in dat house up de block dat we jest passed. Whatcha say we does de monkey up an' freezes onto some of de junk? It brings lotsa jack."

Second Yegg—"Fer de luvva Pete, hang offa dat! Dontcha know dat kinda stuff is woise dan snitchin' candy off'n a bawlin' brat? Dem radio nuts raise all cane when dere wives even dust dem blame tings off. D'ya wanta raise de neighborhood? Dese guys sits up till mornin' t'hear de blame stuff."

First Yegg—"Huh, howdayagetdatway? How d'ya know?"

Second Yegg—"'Cause I got one of dem tings meself. Now laugh dat off!"

500 Attend Milwaukee Radio Amateurs' Club Affair

BEFORE an audience of 500, many being broadcast listeners, the Milwaukee Radio Amateurs' Club, Inc., recently exhibited the two-reel radio film, "The Wizardry of Wireless." Following the exhibition, A. R. R. L. City Manager I. H. Strassman, 9AHO, and E. T. Howell, Sc. M., technical committee chairman, addressed the gathering on the subject of the relations between the amateurs and the radiophone people. The progress being made in ridding the air of unlicensed stations was reported, and the efforts of the traffic committee to bring about cordial feeling between the two classes was called to the assembly's attention as well as a description given of that committee's work.

"Radio Frequency Amplification System" was the title of a paper presented by E. D. Nunn, ex-9FE, a Milwaukee radio engineer, in which stress was laid on the use of R. F. amplification with two variometer receptors. This lecture is the first of a series being arranged by the new program committee chairman, H. F. Waring, pre-war 9AEX, and president of the society. H. P. S. Day, Sc. B., a telephone engineer, presented the second paper under the title of "Vacuum Tube Characteristics." In non-technical language some of the fundamentals as well as the applications of the thermionic valve were treated in interesting fashion.

Upon his return from San Francisco, Charles S. Polacheck, a former secretary-treasurer, addressed the members under the title of "Some Experiences of a Wayfaring 'Ham' in the West," and told of his meeting with a former speaker at the club, L. E Grogan, formerly radio engineer to the government of Southern China; also he related his experiences as a guest of the San Francisco Radio Club, Inc., at several of their interesting meetings.

The club's code class for faddists is meeting weekly at 7:15 p. m., Thursdays, in the Public Museum's Trustees' Room, while the society's regular meeting is held at 8:00 p. m. in the same room and on the same evening.

Amateurs to Broadcast News

E. H. SCHNELL, Hartford, Conn., traffic manager of the American Radio Relay League, has authorized the appointment of 125 amateur stations for the distribution of amateur news items by radio. During recent storm emergencies in the upper Mississippi Valley both amateur operators and broadcasting stations supplemented wire service, temporarily out of commission, enabling a number of papers to keep in touch with news centers and correspondents. Whenever such emergency occurs again in any part of the country these amateur stations will be at the service of railroads, newspapers and the public.

Na-ald De Luxe No. 400

It's the contact that counts

The dual-wipe contact strips of the Na-ald De Luxe socket avoid the trouble experienced with the socket of conventional design. Because of thorough cure and high dielectric properties this socket keeps plate to grid losses at a minimum (of particular importance in Flewelling Circuit or in Radio Frequency).

Price 75 cents

The Na-ald Special Socket No. 499 is a sturdy little socket for the G. E. No. 199 dry-cell tube. It has special slot construction, and is moulded of genuine Bakelite. The heat from soldering connections will not affect these sockets.

Price 50 cents

Booklet with wiring design and instructions for Hazeltine's Neutrodyne circuit, together with other selected circuits, packed with each Na-ald product or sent in exchange for cover taken from any Na-ald carton.

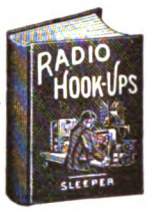
IF YOU ARE INTERESTED IN RADIO YOU NEED THESE BOOKS

Radio Books for the Expert and Amateur

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Radio Hook-Ups

By M. B. SLEEPER

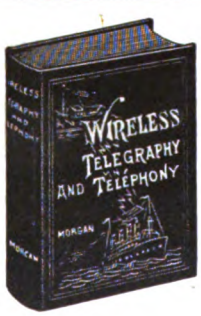
A book that gives you not only clear diagrams for all kinds of telephone and telegraph receiving and transmitting sets, but simple descriptions of each circuit shown and spaces for notes of results obtained.

PRICE 75c.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

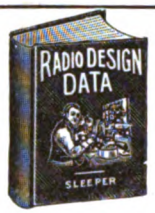
There is a peculiar fascination about receiving radio messages from the high power stations of England, France, Germany, Russia and Italy, as well as those located in the Pacific Ocean and the Oriental countries. Several types of simple receiving sets for this purpose are described, with detectors and amplifiers to accompany them. Suggestions are also given for operating relays and reproducing the signals on a phonograph. Schedules of operating time for high-powered stations are given. In addition, there is some valuable data on home-made wavemeters for testing and experimenting ..... PRICE 75c.



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings ..... PRICE $1.50



Design Data for Radio Transmitters and Receivers

By M. B. SLEEPER

The only book that gives tables and data for designing, receiving and transmitting apparatus so that you need no knowledge of mathematics. It's the first book a beginner buys after he has learned the use of his phone receiver..... PRICE 75c.

Construction of Radiophone and Telegraph Receivers for Beginners

By M. B. SLEEPER

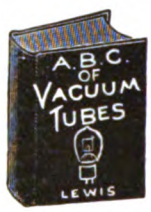
The man who wants to feel the real thrill of accomplishment, and who is not satisfied in the merely making use of what others have done for him, builds his own radio apparatus. Radio men can follow the data in "Radio Phone and Telegraph Receivers" with full confidence, because each piece of apparatus described was first made, tested and found efficient before the final design was accepted. Special receivers, both crystal and audion, are shown in detail. Regenerative circuits as well as audio and radio frequency amplifiers are described with clear photos, diagrams, and working drawings prepared especially for the novice and the man who wants to receive the radio telephone broadcast. A special feature is the phonograph type radio set and the loud speaker. Fully illustrated..... PRICE 75c.

The Radio Experimenter's Handbook

By M. B. SLEEPER

Throughout the preparation of this book, one purpose was kept in mind—Answer the Practical Questions of the "Novice," of the "Beginner," and the more advanced "Student." This book will help in the selection or construction of simple apparatus for the transmission and reception of radio telegraph and telephone signals. In the chapters on radio receivers the simplest crystal, the simple audion, and the regenerative types are described in quite some detail. The question of antennas, both for transmitting and receiving, are taken up. A good many helpful suggestions are given which will be of considerable aid to the experimenter. 16 chapters. Fully illustrated.

PRICE $1.00



The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

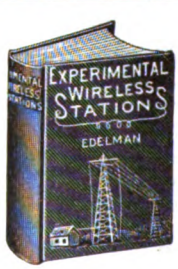
Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated..... PRICE $1.00

How to Make Commercial Type Radio Apparatus

By M. B. SLEEPER

This book describes in detail many commercial types of spark and vacuum tube telephone transmitting and telegraph and phone receiving equipment of all kinds. The experimenter will be able to get a world of ideas for the design and construction of his next piece of radio equipment from the very clear descriptions and the 98 clearly illustrated figures..... PRICE 75c.



Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations..... PRICE $3.00

General Electric Making Collection of Vacuum Tubes

DURING an address on "Radiotrons" by W. C. White, of the General Electric Company's Research Laboratory, which recently was broadcast from WGY, Mr. White made the following interesting appeal to radio fans:

"For some time past, we have been making a collection of vacuum tubes to illustrate the development of this interesting art. A number of years from now such a collection will be of great interest and of considerable historical value.

"We would like to ask radio fans to assist us in making more complete this vacuum tube collection.

"It is natural, however, that we are only desirous of obtaining additions to this collection and, therefore, are interested only in tubes of other than General Electric manufacture. What we desire to obtain are tubes of very early manufacture, tubes of unusual design and those of other countries, particularly Italian, Japanese and German. It is not essential that these tubes be in operating condition. The filament may be burned out or the vacuum impaired, but they should be in satisfactory mechanical condition.

"If any radio fans have such vacuum tubes I shall be very glad to have them write me, describing their tubes briefly and if they form an addition to our collection we will write their present owners offering them on receipt of their tubes to send them in exchange for each one of interest to us, one of the new UV-199 radiotron tubes. We will also include a socket for each tube and complete operating instructions. Address all communication relative to tubes of possible interest to us for this collection to WGY, General Electric Company, Schenectady, New York.

"It is particularly requested that any who have such tubes should write first and wait for a letter from us before shipping their tubes to us to learn whether they have any historical interest as an addition to our collection."

Newspaper Publishers Appoint Radio Committee

AT the recent annual convention of the American Newspaper Publishers' Association, held in New York City, a committee was appointed to study the radio questions which had been discussed by the convention, such as whether radio broadcasting programs in news columns are not free advertising, and to report at the 1924 convention. C. P. J. Mooney, of the Memphis, Tenn., *Commercial Appeal*, was named as chairman. The other members are: W. A. Strong, Chicago *Daily News;* E. B. Piper, Portland, Oregon, *Oregonian;* Daniel Nicoll, New York *Mail;* Louis Hannoch, Newark *Sunday Call;* Harry Chandler, Los Angeles *Times;* Elzey Roberts, St. Louis *Star;* Rowe Stewart, Philadelphia *Record;* Amon G. Carter, Fort Worth, Texas, *Star-Telegram,* and H. S. Scott, Detroit *News.*

Holland Opens Powerful Radio Stations

WHAT are claimed to be two of the most powerful radio stations in the world have just been opened at Kootwyk, Holland, and at Bandoeng, Java, in the Dutch East Indies. They are 7,500 miles apart and each occupies an area of 750 acres. The most satisfactory wave length so far determined by experiment is 8,400 meters for use after sundown. During the day better results were obtained on 16,800 meters. The stations were built by the Telefunken Company after the plans of the big wireless plant at Nauen, Germany. Politically considered, Holland may now communicate with her distant colo-

The Height of Efficiency
Crosley Model X—Price $55

Clearly, distinctly, as though given in the same room, messages from W. L. W. Broadcasting Station, Crosley Mfg. Co., Cincinnati, are heard in all parts of America if a Crosley Model X—a four-tube radio frequency set—is used. This remarkable instrument, very easy to tune, simple and beautiful in construction, has repeatedly brought in messages over 4,900 miles away.

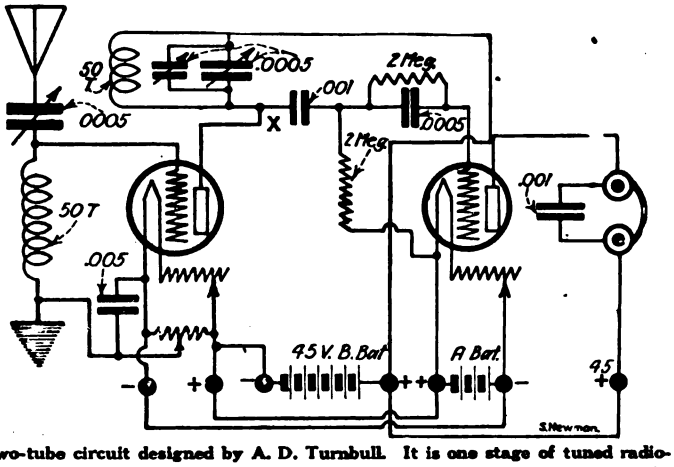
From Nova Scotia to Los Angeles with This Two Tube Set

By A. D. Turnbull

SEEING various diagrams and circuits that many of your readers send in I thought perhaps they would be interested in my two tube receiver with which I have done some very fine work. It is simple and very selective and besides being sensitive, it does not need an electrical engineer to figure it out or work it.

It can be seen from the illustration that it is a combination of the single circuit regenerative circuit with one stage of tuned radio-frequency. The variable condenser in the antenna circuit is an A. B. C. 23 plate, but any other good one will do. The tuning inductance in my set is a variometer with 50 turns on both stator and rotor. This variometer is split using the unit as a coupler, the rotor being used as a tickler and the stator as antenna inductance, the fine tuning being accomplished by means of the antenna condenser. I have found that it is best to buy the variometer and then separate the connections between the rotor and stator, rather than make your own as besides being a hard job, the variometers you purchase are always more reliable as to workmanship—that is unless you have a lathe, can turn your stator out and make a former to wind the wire on.



Two-tube circuit designed by A. D. Turnbull. It is one stage of tuned radio-frequency, in combination with a single circuit regenerative, and is remarkably selective and sensitive.

A Canadian R-215A dry cell tube is used, with a Klosner 200 ohm potentiometer across the filament lead of the first tube. I have experimented with both the common A leads, and separate batteries for each tube, and find that the difference is so slight that it does not matter. I advise using one battery so as to save both trouble in wiring and also the expense of a separate set of batteries. For good work a very fine control rheostat should be used, preferably one of the carbon unit type, such as the Bradleystat. This is one of the most important controls of the entire circuit and it is absolutely necessary to good work that fine control of the filament current be had.

Although this circuit will give wonderful results on 45, I have found it necessary to use higher voltage, especially when doing real distance work. Then sixty volts should be used on the plate.

The fixed condensers are all mica insulated and should be the best you can buy as you will benefit much more by using good apparatus in this circuit as well as any other.

The values of the different condensers are as follows: Phone condenser .001mfd.; grid, .0002mfd.; potentiometer-filament condenser, .005mfd.; condenser in plate circuit of first tube (critical) .001mfd. The grid leaks are not at all critical, but I have found that by using the popular variable type, the best capacity can very easily be found and once found will remain constant for a given tube. This eliminates considerable tuning.

When the set is wired trace your connections and see that they are all O. K. before turning on the tubes. Then, turning the potentiometer to the negative side of the filament circuit, turn on the filaments and if oscillations are not immediately noticed reverse your rotor leads. Place your plate condenser at approximately 90°, and tune in with the antenna condenser. Outside of tuning the plate coil (rotor) to resonance by means of the condenser, the tuning on this circuit is exactly the same as any other single circuit regenerative. In tuning the plate coil first get your station in and then bring it in louder with your condenser and vernier, keeping constant watch on the filament current and turning it down if the set oscillates too violently, which will destroy the brilliance and tone of the signals.

With this circuit and two dry cell tubes I have copied the following stations from Sydney, N. S., Canada:

When I say copied, I do not mean simply hearing the call, but either the whole, or part of a program. KHJ Los Angeles and 2LO London, England, are the two extremes. In between these I have copied: WOAI, WFAA, WBAP, WPA, Texas; WKAF, Denver, Colo.; WSB, Atlanta, Ga.; PWX, Havana, Cuba.

I think that with this set working properly and using the best apparatus obtainable anyone who constructs it will be pleasurably surprised at the distance he can get and the selectivity and freedom from noise which is one of the noticeable features of this little circuit.

Radiophone Broadcasting Committee, Second District, Decides on Wave Lengths Effective May 15

THE conference, composed of the members of the Radiophone Broadcasting Committee, was held at the U. S. Custom House, New York City, to inform the broadcasting interests concerning the new classifications of broadcasting stations to be hereinafter known as Classes A, B and C. The necessary requirements, together with a resume of the new plans governing broadcasting stations in the Second District was carefully gone into, and a new time schedule of operation established. The following representatives were present:

American Telephone & Telegraph Co.—A. H. Griswold, W. E. Harkness, E. Miller, R. Brown; L. Bamberger & Co.—Edgar Bamberger, W. S. Moler, J. R. Poppele; Calvary Baptist Church—George F. Koster; De Forest Radio Tel. & Tel. Co.—G. C. Crom; General Electric Co.—M. P. Rice, Harry Sadenwater; D. W. May & Co.—D. W. May, William Brough; I. R. Nelson & Co.—I. R. Nelson, Jr., R. H. Horning; New York Police Department—M. R. Brennan; Radio Corporation of America—Dr. Alfred J. Goldsmith, J. Weinberger, W. A. Graham; Westinghouse Elec. & Mfg. Co.—W. H. Easton, C. W. Horn, Charles B. Popenoe; New York City (Municipality)—R. Atchison; Peoples' Pulpit Association—H. C. Kuser; Radio Shop of Newark—H. Lubinsky; Rensselaer Polytechnic Institute—Prof. W. J. Williams; Ridgewood Times Publishing Co.—George Schubel, William Boettcher; Seventh Day Adventist Church—Dr. C. B. Haynes, L. K. Dickson; Ship Owners' Radio Service—J. B. Ferguson, D. M. Kendall; H. C. Spratley Radio Co.—H. C. Spratley; Tarrytown Radio Research Laboratory—Frederick Koenig; Union College—M. P. Rice; Wireless Phone Corporation—J. O'Connor; Western Electric Co.—O. M. Glunt, N. H. Slaughter. Observers: E. N. Davis, United Press; O. E. Dunlop, Radio Editor, New York Times; F. P. Guthrie, U. S. Shipping Board, Washington, D. C.; C. B. Cooper, C. B. Cooper Co.

The following articles of agreement were drawn up:

1. That the committee, known as the Inter-Company Radiophone Broadcasting Committee of the Second District, continue its activities and that Arthur Batcheller, United States Supervisor of Radio, in charge of the Second District, remain as chairman.

2. That the hours most suitable for broadcasting are those between 9:00 a. m. and 12:00 midnight daily.

3. No experimental transmission work on radiating antennae on wave lengths between 200 and 1,000 meters will be permitted between the hours of 11:30 a. m. and 12:00 midnight, local standard time.

4. It was agreed that where a number of Class "A" stations could operate simultaneously on the same wave length without causing interference, that this practice should be permitted.

The following resolution, introduced by M. P. Rice, of the General Electric Company, seconded by Dr. Alfred N. Goldsmith, of the Radio Corporation of America, was unanimously adopted:

RESOLVED: In the judgment of the Radiophone Broadcasting Committee of the Second District, the useful operating time on all Class "B" waves is so fully occupied by suitable broadcasting station schedules that the committee respectfully petitions the Secretary of Commerce, in the public interest, that no further licenses on these wave lengths, during the time mentioned, be granted.

The following resolution introduced by W. S. Moler, of L. Bamberger & Company, seconded by A. H. Griswold, of the American Telephone & Telegraph Company, was unanimously adopted:

RESOLVED: That this conference go on record with a rising vote of appreciation to Secretary Hoover for his efforts and the co-operation extended by Arthur Batcheller, U. S. Supervisor of Radio, in charge of the Second District, in effecting an amicable adjustment of the broadcasting situation in this district, and that a copy of this resolution be forwarded to the Secretary of Commerce and to the press.

The following time schedules of radiophone broadcasting stations was adopted:

This Compact Receiver Gets What Others Miss

By Loring Coes

IN RADIO WORLD for April 28 I notice an article on "A Compact Universal Receiver." I am enclosing two photos showing a small set employing the same circuit, which I have been using for nearly a year. It is the most consistent performer and the simplest set to operate that I have ever seen. I keep the set on the desk and when I want to find out what the other sets are missing I hook it up.

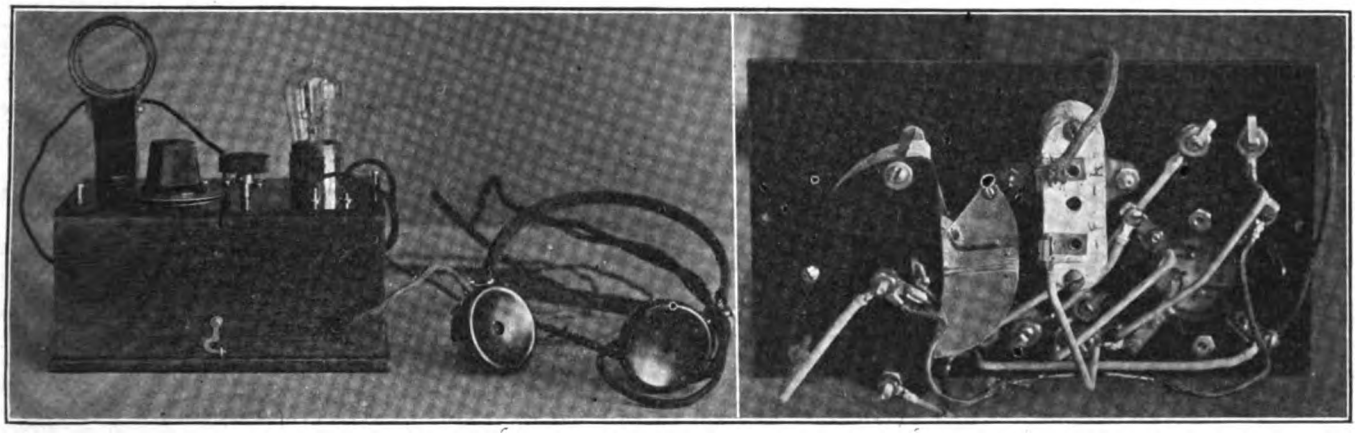
The case is an old medical vibrator case, and the panel is 4¾ x 7. Six cord jacks and two leads (A battery) make the connections. I decided to use a separate terminal for each battery connection, because the switching of polarity, especially on long waves, is sometimes a great help. I do not use a phone condenser, and no leak on broadcast stations. Over 2,000 meters call for a one meg. leak.

The grid condenser is mounted on the case and in the photo the two free wires at the bottom are the connections for the leak. The rheostat is the vital factor and the connections to the honeycomb must be right.

Since the photos were made I have lined the case with 40 gauge and grounded it, which effectively kills all capacity effects.

With an aerial 110 feet long I have heard stations up to 1,800 miles distant, including WKAQ at San Juan and PWX at Havana. Kansas City, Atlanta and Chicago stations are heard regularly. Recently I constructed a similar set adding two stages AF, and the results are more than satisfactory.

I have rewired this set three times, trying each time to cut down the footage, and have finally got it down to 31 inches of bus bar without the external battery leads. I hope this may interest someone planning a similar set.



Two views of Mr. Coes's compact, simple and efficient receiving set.

Radio Makes Every Sea Captain Own Forecaster

WITHIN a short time "skippers" of ocean going vessels equipped with radio will be making their own forecasts and weather maps daily, according to Chief Forecaster Edward H. Bowie, of the U. S. Weather Bureau. This is due primarily to efficient and immediate radio service.

Since his return from a long trip on the Atlantic ocean in the French ship "Jacques Cartier," Mr. Bowie is very enthusiastic over the prospects of forecasting at sea, and urges its practice on American vessels. With the vast amount of meteorological information broadcast today from practically all large radio stations and many ships it is possible, he says, for masters of vessels to make their own forecasts and even make a daily plot of weather conditions, just as is done in the Weather Bureau in Washington. The Naval radio station at Arlington sends out daily a general report from North America and in return receives a similar report from Paris on European conditions.

Since most storms journey eastward, a "skipper" in the Atlantic knows generally what is coming and by keeping in touch with vessels west of him he can do his own forecasting. In turn, he keeps other ships posted as to conditions in his location.

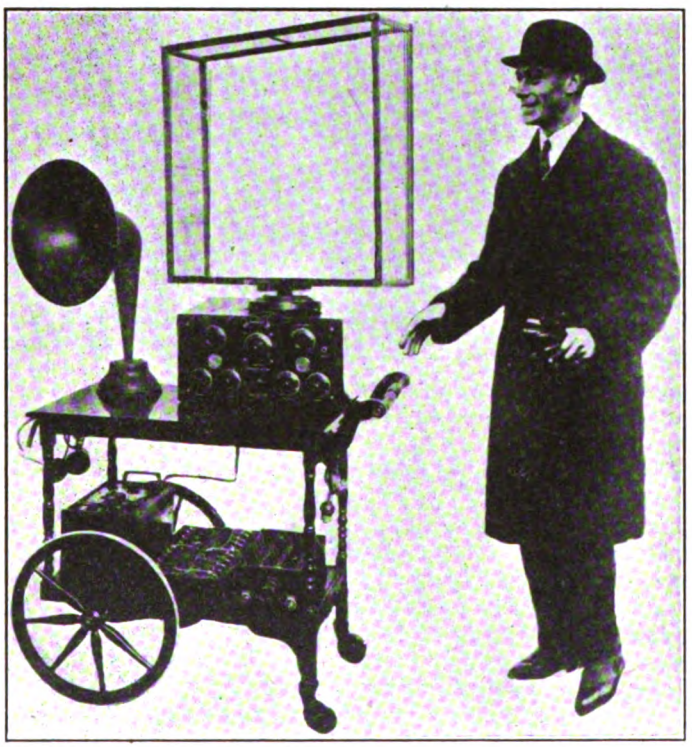
Elementary Instruction for the New Army of Radio Beginners

Constantly Used Terms Explained in Plain Language for the New Radio Enthusiast

By Lynn Brooks

AUDIO-FREQUENCY TRANSFORMER: A transformer used to step up the small amounts of current flowing in the detector circuit. It consists of an iron or steel core, generally taking the shape of a square and surrounding the coil entirely, with a center bar of laminated iron or steel running through the winding. The primary is wound



(C. Underwood and Underwood)

The Duke of York and the de luxe receiver he acquired as a wedding present from New York. The set is a portabloop receiver and all the trimmings are of gold. It is mounted on a mahogany teacart and is complete in all details even to having a charger for the storage battery underneath.

over this center core, using very fine wire and waxed or impregnated paper between layers. Then over this primary is wound the secondary. Upon the ratio depends the number of turns that are wound upon this coil. Most transformers run about five to one, meaning that there is a ratio of five turns on the secondary to one on the primary. Some transformers run lower than this, having a ratio of three to one, and some run as high as twelve to one. These high-ratio transformers are not used much in anything but the first step. A transformer of nine to one in the first step and then three to one in the second step is the usual method of procedure. This does not apply for all cases, as with some tubes better results are obtained if transformers of fairly low ratio are used through the entire circuit.

B BATTERY: In order properly to operate a tube detector, or amplifier, it is absolutely essential that there be some means of putting a fairly high positive potential on the plate. The most common and economical way of doing this is to supply the circuit with high voltage from a series of small cells hooked or connected in series. It is well known that when cells are hooked in series that the voltage (pressure) varies as the number of cells, but the amperage remains that of any one of the cells in the group. The most common method of dealing with the battery problem has been to connect in series a number (generally 15) of very small dry batteries, setting them in an impregnated cardboard box and pouring melted compound around them to make them solid. The life of such a battery is necessarily limited, but even at that it is surprisingly long, a series of cells often lasting from nine months to a year, using the set for a couple of hours per evening. This is easily understood, however, when it is stated that, for most tubes, the plate will not use more than .6 or .8 milliamperes at the most, which is a very small amount. In storage cells (which have the advantage of always being charged if a little care is taken) there are 10 or 20 cells hooked in series, depending upon the voltage desired. These cells are exact replicas of their larger and more powerful brothers, the only difference being the plate surface, which is the governing factor of a battery's amperage or power feature. With these batteries it is, of course, not necessary to throw the battery away when it is run down, but it is necessary to recharge it through the agency of a rectifier if A. C. current is used, or a bank of lamps if D. C. current is at hand.

A BATTERY. In order to heat the filament of a tube some method of bringing the filament to incandescence must be available. This is because of the fact that, when the filament is heated, it has the property of throwing off electrons, which, as stated in a previous issue, perform the action of taxies for the electrical impulses that are waiting to jump across to the plate. If the tube used is of the six-volt type you must use a battery that will furnish sufficient current to heat the filament, and at the same time use one that will last. That is the reason for using the storage battery. It will furnish the desired current and give better and longer service than the dry cell, although four dry cells in series will furnish the tube with sufficient current to light it. The determining factor in this case is time and expense. With a storage battery the initial expense is ten or fifteen times as great as the dry cells, but when it is considered that, with the dry cells, you would probably get about 25 or 30 active hours' service you can easily see that the constant replenishing of the cells would be of greater eventual expense than the original cost of the storage cell. With the popular dry cell, or 1½-volt tube, it is a much easier matter to supply the filament current. The most common method is to use three to six dry cells hooked in parallel, the voltage remaining constantly 1½, but having the advantage of heavy amperage and consequently longer use. The new tubes consume very little current, using from .2 to as low as .06 ampere on some of the tubes.

PORTABLE SETS: During the summer months the portable sets come into great use. Now that the small tubes have become popular and do not necessitate large batteries it is possible to incorporate tube sets where it was only possible to take crystal sets heretofore. The filament can be supplied from three flashlight cells in series, and the plate battery from a small bloc-type, high-voltage battery.

VARIOMETER: A continuous inductance, the tuning of which is accomplished by tuning a rotor inside of the stator. The principle on which this apparatus works is that with two coils, the windings of which run concentrically, the inductance effect is minimum, as the induction field in each helps the other. As the rotor is turned, this field in each coil interferes with the other and the wave length to which the coils will correspond is raised. When the induction fields of both coils directly oppose each other the maximum is reached

A Radiophone and Receiving Set Combined

By Carl Masson

WHEN the wave of radiophone popularity swept the world a little over a year ago, many new radio amateurs were born. First they were content with simple crystal receiving sets, but every real radio bug soon outgrows his first set, and that is why radio dealers are finding a new demand for parts comprised in the advanced V. T. circuits.

No doubt many of the "new arrivals" are now "dyed in the wool" to such an extent that they are contemplating the construction of a transmitting outfit. It is for the benefits of such amateurs that this article is written.

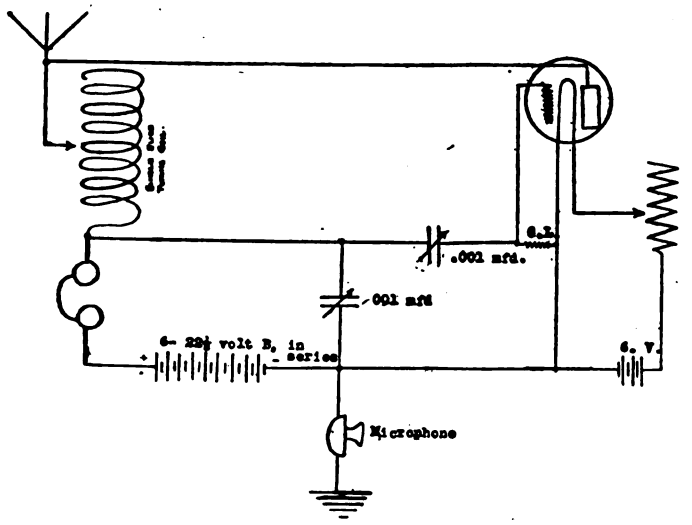

Fig. 1—Circuit diagram for a combined receiver and transmitter. When constructing this set it is best to use either a five-watt tube or one of the hard tubes, as better results will be secured.

a radiophone is because of the great expense and complicated apparatus usually attached to it. I am sure that this article overcomes both of these objections.

The drawings show a radio telephone capable of transmitting the voice a distance of 5 miles under good conditions. This outfit also has another advantage: It also may be used as a receiving set without any changes. The operator can hear the incoming signals while talking. He also can tell when the transmitter is properly tuned, as he can hear his own voice in the phones.

Now to get to the constructional details of the outfit. The panel should be of bakelite, or some other insulating material that is equally as good, and should measure 12x12x3/16 inches. This is supported by a wooden base. A single slide tuner serves as the inductance although, if desired, the constructer can wind a coil, taking taps to a switch on the panel, which may be more convenient. The coil should be about 12 inches long, 5 inches in diameter and wound with No. 28 D. C. C. wire, taking taps at every tenth turn.

The microphone is of the ordinary type. If desired, the hand style may be supplemented in place of the mounted one. The variable condensers, as stated in the circuit, are .001 mfd. in capacity.

The grid leak can be easily home-made. A piece of thin cardboard, 2 inches long and ⅛ inch wide should be soaked in India ink and mounted on a small block, with binding posts at each end.

The rheostat is the 10 ohm filament type. The V. T. is one of the "hard" type. One of the amplifying type of standard makes of tubes will serve quite well.

The plate voltage is obtained by connecting six 22½ volt "B" batteries in series, making a total of 135 volts. Although these "B" batteries are quite expensive, they will last a reasonable length of time. The filament

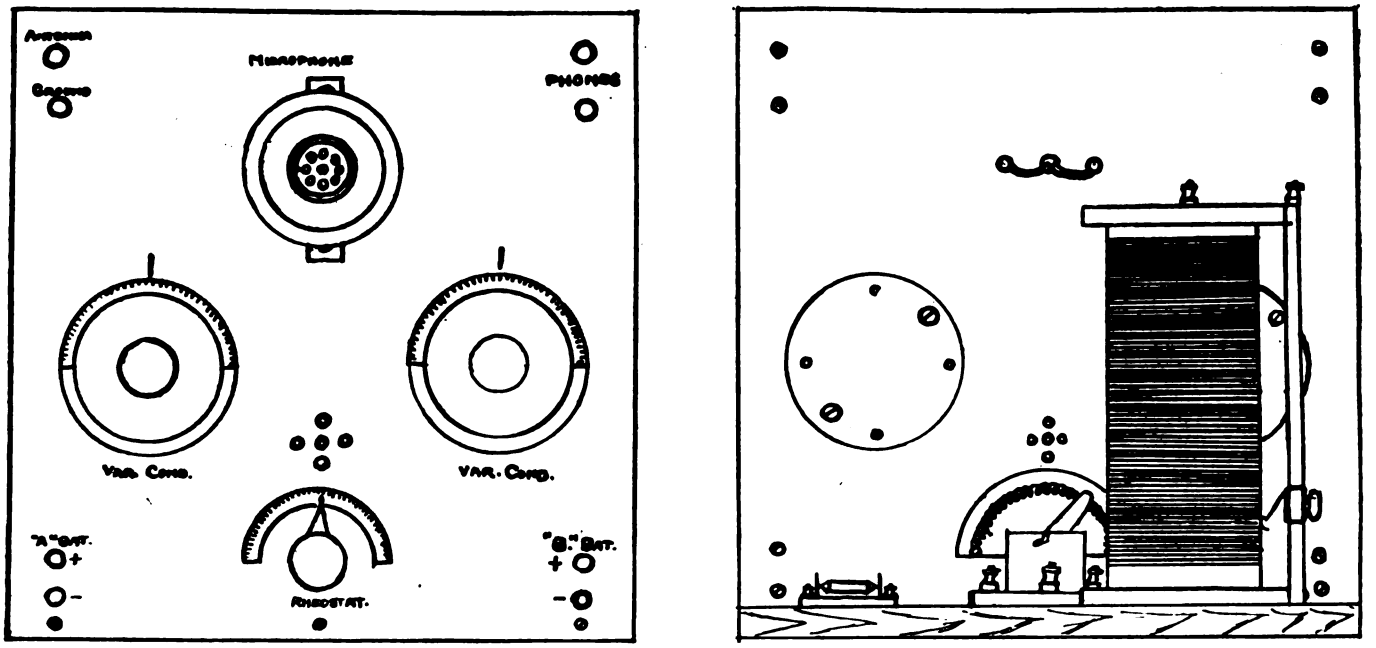

Fig. 2—Front and rear views of the panel, showing layout. The tuner is set because when transmitting a certain wave length is desired. For receiving, fine tuning can be accomplished with the condensers.

While many old timers may prefer the dot and dash method of ether communication, I believe the modern amateur who was born with the radiophone will naturally uphold it. The real reason why many amateur transmitters have turned their backs on constructing

voltage is the regular six volts—preferably from a storage battery.

The phones should always remain in the circuit while the outfit is in operation. They are connected between

Broadcasters Number 590—Name Wave Assignments

By Washington R. Service

WASHINGTON—The process of allocating new wave lengths and re-classifying radio broadcasting stations is a slow one. Department of Commerce radio officials do not expect to be able to issue a complete list of the three classes of stations with their wave lengths after May 15.

On May 4 there was a total of 590 broadcasting stations, including 32 A, 30 B and 528 C stations. During the last month 23 new stations were licensed, 10 were transferred from Class C on 360 meters to Class A, and 14 were dropped from the department's lists.

Sixteen new stations in eleven different states were licensed during the past week. Among them were two churches, two colleges, a high school, a military unit and a newspaper.

First Portable Radio Set Using Flashlight Batteries

A COMPACT, self-contained portable radio receiving set which can be carried as easily as a suit case, which requires only flashlight batteries for the filaments of the tubes and which weighs less than 18 pounds, has been perfected by the General Electric Company for the Radio Corporation of America. An outstanding feature of this set, adding to its portability and desirability for camping trips, is the fact that the new radiotrons UV-199 are used which require only 60 milliamperes (.06 amperes) filament current per tube.

This new outfit, known as the Radiola II, will receive radio messages over a range from 200 to 600 meters for a distance as great as any set having a detector and one stage of amplification. It is housed in a mahogany cabinet with hinged front and rear covers. Head telephones with plug attached are clamped on the inside of the front cover. Provision is made in the rear cover for batteries in such a way that they can be easily exchanged. The set is so designed as to make a neat appearance in the home. The front cover can be readily detached.

Radiola II comprises a regenerative receiver with a vacuum tube detector and one stage of audio frequency amplification. The circuit is very efficient and will operate a loud speaker on signals received from nearby stations. With an additional amplifier, it can be used to obtain loud speaker signals from distant stations.

For portable use the filament current is supplied from two 3-cell, 4½ volt flashlight batteries in parallel, and the plate or "B" battery current is supplied by two 22½ volt batteries connected in series. For home use, when weight and portability are not essential, larger batteries for filament and plate current can be used.

An Improved Grimes Reflex Circuit

By W. S. Thompson, E.E.

NOW that winter is over and summer nearly here the radio fan can expect that atmospheric conditions will make receiving difficult. In fact, the author has found that, even at present, disturbance is very noticeable at times, making the use of a loop for picking up signals necessary for good reception. The hook-up given in Fig. 1 is for a reflex circuit, which will enable the user to get a good range even when atmospherics are at their worst.

Since writing the two articles on reflex circuits, published some time ago in RADIO WORLD, I have tried out several new ideas, which have been developed since that time, and have found that the set herein described gives the finest results, and to me is the best reflex I have ever heard. The main points wherein this hook-up differs from those previously described are: The order in which the tubes are used as audio-frequency amplifiers and the method of preventing the tubes from oscillating. It will be noticed that the third tube is used as the third stage of radio-frequency amplification and as the first stage of audio-frequency amplification, while the second tube is the second stage of both audio- and radio-frequency amplification. Credit for this arrangement is due to Mr. David Grimes, of Staten Island, New York, who has developed this method of reflexing signals.

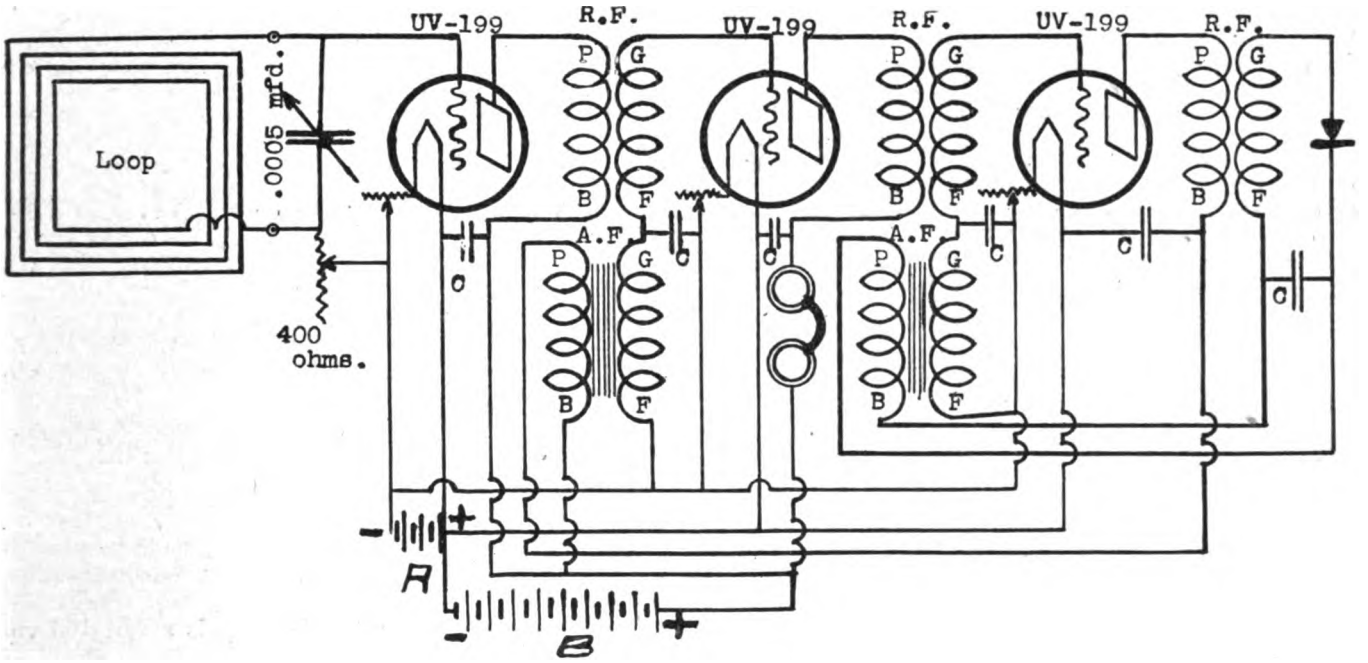

Fig. 1. Hook-up of Mr. Thompson's improved Grimes reflex circuit.

The advantages of this new development are very important when the elimination of static and other forms of interference are considered. It should be noted that any outside noise, such as an induction hum from power lines, will be amplified in audio-frequency through several tubes and then go to the phones in the straight reflex circuit; while in this type there are no stages of audio-frequency amplification in cascade between the loop and the phones. In addition the first stages of radio-frequency amplification tend to strain out any 60-cycle hum which may be picked up by the loop. This fact in itself is a big advantage over the La Tour circuit; but, in addition, there are several other advantages which are equally important. In the previous hook-ups shown any radio-frequency waves which leak through the detector are impressed upon the grid of the first or second tube and are again amplified at radio-frequency. This state of affairs causes the set to oscillate, making stabilization very difficult. It should also be noted that, in the Grimes method, the leakage radio-frequency waves go through only one stage of radio-frequency before going to the detector, thus eliminating a factor which tends to cause the tubes to oscillate, making the set very stable. A third advantage lies in the fact that the heaviest audio-frequency currents are impressed upon the grid of a tube which does not receive the heaviest radio-frequency currents. This equalizes the load carried by each tube, so there is no chance of one tube becoming paralyzed due to an overload.

Still another advantage lies in the way the by-pass condensers are connected, for they by-pass the radio-frequency waves around, not only the audio-frequency transformers, but also the "B" battery. This keeps the audio- and radio-frequency waves more completely separated, and again reduces the tendency towards oscillating tubes. The stabilizer, which consists of a 400-ohm potentiometer connected in the grid circuit of the first tube, will allow the set to pick up local broadcasters without any difficulty, due to oscillating tubes. This means of stabilizing gives an undistorted amplification, which is sometimes difficult to obtain when stabilizing by changing the normal potential of the grid.

A disadvantage of the Grimes circuit, which has been overcome in the hook-up shown in Fig. 1, is that the maximum audio-frequency currents were impressed upon the grid of the first radio-frequency amplifying tube, thus making it less sensitive to weak radio-frequency waves. By placing one stage of pure radio-frequency amplification before the reflex tubes the second tube is better able to amplify both waves. Another advantage lies in replacing the tube detector with the crystal, for, in addition to the advantages of a crystal as a detector, it has a particular advantage in this circuit because the radio-frequency leak-

Radio Personnel in Navy Totals 2,419

By Carl H. Butman

AN exhaustive study of the radio personnel situation in the Navy is now under way both afloat and ashore, in an effort to increase the efficiency of Naval Communications. Some of the less important shore establishments have been closed and the personnel sent to busy stations where shortages existed or to ships at sea which were in need of new operators and experienced radio men.

The training of radio men now in Naval schools is to be pushed, it is understood, with a hope of relieving all shortages by July 1. Previously all third class radio men were at once assigned to fleet work for military training, with the result that the ships-of-war were deprived of a number of higher rates, including first class men and chiefs. This matter is now being adjusted so that some third class men will be assigned to shore duty. In the near future many transfers will be made between the fleets and shore stations to adjust the situation.

On March 31 there were 2,419 radio men in the Naval service, 463 short of the full complement. They included 466 chiefs, 421 first class, 433 second class, and 1,099 third class radio men. In view of the fact that the shortages all occur in the higher rates, over 400 men are now in line for promotion to second class rates or higher, and prospects for their advancement are said to be good. Third class men receive $60 per month; second class, $72; first class, $84, and chiefs from $99 to $126.

At the Navy's five shore radio training stations, 612 men are now undergoing instruction. The largest training school is at Great Lakes, Mich., where over 400 men are studying, the balance of the students being distributed between Hampton Roads and San Francisco, while eight men specializing in sound work are at New London, Conn. The education of these men in modern radio operation and new developments goes on continually, even after they are rated. A recent report from the Charleston district states that study and training in communication instruction and regulations, traffic and text books on several phases of the radio telephone and telegraph arts is carried out daily.

Some idea of what the Navy is trying to achieve in efficiency is gained from a statement of "deficiencies" in communication, which relates that out of 130,942 official messages, not including routine broadcasts for other departments, 26 mistakes were charged to the Naval radio service. These included undue delays, incorrect routing and errors in coding and decoding over a period of eight months.

Catches a Stray Radio Concert

By Will M. Cressy

BEING probably the only he-human-being in the United States over six years old who is not an expert on radio, I do not know whether this happening possesses any interest to you or your readers; but it sure struck me as being strange, to say the least.

At the Orpheum Theatre, Des Moines, Ia., there is a telephone that runs from the stage to the box office. It goes nowhere else; has no connection with any other wires running outside the building.

The other night I took the receiver down from the phone on the stage to call up the box office. And for the next ten minutes we listened to as fine a radio concert as one could wish.

I do not know where it came from, where it was going, or how it got on to that wire. Perhaps you do.

(*Continued from preceding page*)

age through the crystal is very much less than through a tube, hence making the circuit more stable. The advantages of reception in using a loop have been discussed previously, so it will be sufficient to say that static will not interfere with signals as much as when using an outdoor antenna. The loop recommended for this set consists of 20 turns of No. 18 wire wound on a two-foot loop, tuning with a .0005 mfd. condenser.

The best tube to use is the new U.V.-199, which has recently been released for sale. The internal grid-plate capacity of this tube is very small, hence making it well adapted for radio-frequency amplification, and having less tendency to oscillate. When using any tube as an amplifier the best results are usually obtained when the grid is kept negative with respect to the filament. This always holds true if a high plate potential is used, so the filament rheostat of each tube should be connected in the negative lead from the filament battery. By this means the resistance of the rheostat can be used to govern the potential of the grid. When using the U.V.-199 care should be taken that the filament rheostat has enough resistance to prevent excessive currents through the filament.

If a six-volt storage battery is to be used the resistance of the rheostats should be at least 60 ohms, although 30 ohms would be sufficient if three dry cells are used for filament lighting. In hooking up the set the experimenter should note carefully the connections for the by-pass condensers, marked "C" in Fig. 1. These condensers should have a capacity of about .002 mfd. for best results. The correct voltage for the "B" battery is about 100 volts because the tube recommended will give very satisfactory results when this voltage is used. The potentiometer in the grid circuit of the first tube has one terminal connected to the tuning condenser and the other terminal left free, the movable blade being connected to the minus side of the "A" battery, as shown.

All tuning is done with the condenser shunted around the loop, although the 400-ohm potentiometer will have to be adjusted for each station, depending upon the strength of the signal received. The use of separate rheostats for each tube is recommended for two reasons—separate control of filament brilliancy helps to stabilize the set, and because the resistance of the rheostats keeps the grid of all tubes at the proper potential. It will be found that adjustment of the filament current will be more critical with the U.V.-199 than with other hard amplifying tubes, making the use of separate rheostats advisable. Care should be taken in purchasing radio transformers that the wave length range is broad enough to cover the new broadcasting wave lengths recently assigned. It is recommended that the interchangeable type transformer be used so that higher wave lengths can be reached by plugging in a different set of transformers.

The Radio Mother *By Henry Gillen*

(*Courtesy of the Boston Post*)

We never could educate mother
To give up her old-fashioned way;
A little black bonnet with lavender on it
And a shawl—she was dressed for the day;
The movies she found too exciting
And dances too fancy by far;
She always contended the evening well ended
In making a muffler for pa.

The folks looked too fine at the opera,
The automobile was too fast;
At every new wrinkle her bright eyes would twinkle—
We knew that the die had been cast;
When every one else was out sporting,
And dad had come home from the fights,
We found her there "knittin'" and stroking the kitten,
Until she had put out the lights.

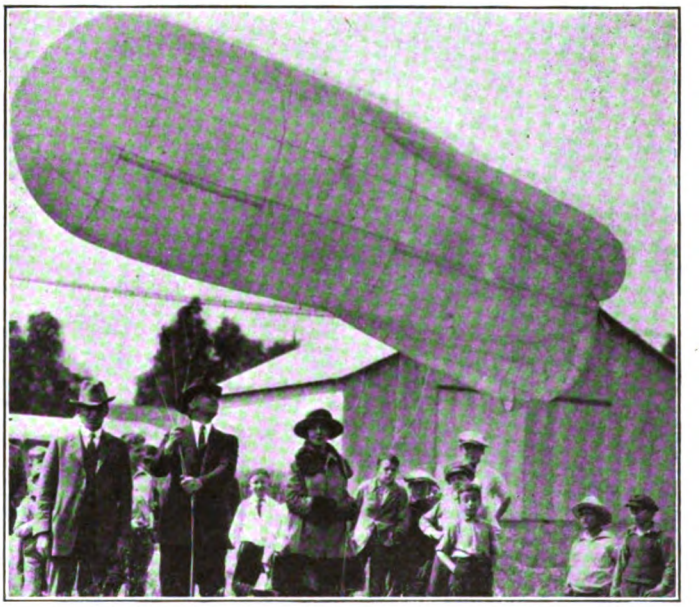
But now when the house is all quiet,
And sewing is hurting her eyes,
She listens to singing the ether is flinging
In mystical waves through the skies;
The crystal receiver won't do her;
She has passed to a triple-tube set,
And has picked up Chicago, but that is not far though;
She hopes to get Seattle yet.

Standard Radio Waves To Be Transmitted from Washington, D. C.

THE Bureau of Standards at Washington, D. C., (Station WWV), transmitted radio signals of standard frequency on the evenings of May 1 and May 7, starting at 11:00 p. m., Eastern Standard Time. The range of frequencies was from 500 to 1,000 kilocycles, corresponding to 600 to 300 meters. It is expected that within the next few weeks higher frequencies will be transmitted to include the waves used by amateurs. These standard frequency signals are intended to be used for standardizing wave meters and adjusting transmitting and receiving apparatus. The proper adjustment of such apparatus is particularly important in connection with the re-allocation of waves as recommended by the Second Radio Conference held in Washington in March, 1923. Considerable interest has been shown in other schedules of such signals which have been transmitted recently from WWV. The schedule of the transmission for both evenings is given below:

Time	Signal	Frequency, Kilocycles per Second	Approximate Wave Length, Meters.
11:00 to 11:04 p.m.	General Call	500	600
11:04 to 11:08 p.m.	Standard Frequency		
11:08 to 11:11 p.m.	Announcement		
11:15 to 11:19 p.m.	General Call	600	500
11:19 to 11:23 p.m.	Standard Frequency		
11:23 to 11:26 p.m.	Announcement		
11:30 to 11:34 p.m.	General Call	700	428
11:34 to 11:38 p.m.	Standard Frequency		
11:38 to 11:41 p.m.	Announcements		
11:45 to 11:49 p.m.	General Call	800	375
11:49 to 11:53 p.m.	Standard Frequency		
11:53 to 11:56 p.m.	Announcement		
12:00 to 12:04 a.m.	General Call	900	333
12:04 to 12:08 a.m.	Standard Frequency		
12:08 to 12:11 a.m.	Announcement		
12:15 to 12:19 a.m.	General Call	1,000	300
12:19 to 12:23 a.m.	Standard Frequency		
12:23 to 12:26 a.m.	Announcement		

The "general call" was given by voice during the first half of the four minute period and by continuous wave telegraph during the second half. This was done to enable listeners to tune in WWV. The "standard frequency signals" consisted of the call letters WWV (. — — . — — . . . —) repeated with very long dashes intervening and were transmitted by unmodulated continuous waves. The "announcements" were made by voice during the first half of the period and by CW telegraphy during the latter half. The general call and the announcements were on the same frequency as the standard frequency signals. Details regarding the utilization of these signals may be obtained upon application to the Bureau of Standards.



(C. P. and A. Photos)

R. W. Coburn and Roy Knabenshue, the aeronautical expert, recently constructed a model balloon on which to suspend their antenna, thus eliminating many disturbances, they claim. The balloon is 14 feet long and holds 150 cubic feet of hydrogen gas.

Coming! New List of Broadcasters!

While the Department of Commerce has assigned wave lengths for each of the broadcasting zones established by the recent Second National Radio Conference, individual assignments of station wave lengths have not been completed. They are being arranged as rapidly as possible and as soon as finished A COMPLETE, UP-TO-DATE LIST OF BROADCASTERS will be published by RADIO WORLD.

The allocation of wave lengths for 16 new Class A stations appears in this issue of RADIO WORLD.

To Use Kilocycles For Designating Radio Waves

THE Second National Radio Conference, which met with Secretary Hoover in March, introduced a method of designating radio waves which is somewhat new to the radio public. This is the use of frequency in kilocycles (abbreviated kc) instead of wave length in meters. The advantages of this practice have been familiar to radio engineers for some time, and it is probable that it will eventually replace the use of wave length in meters. As a matter of fact, wave length is a somewhat artificial conception in the handling of radio apparatus and is one of the difficult things for the beginner to understand. The frequency of the radio wave is the same as the frequency of the alternating current which flows in the radio transmitting or receiving set.

As often happens in technical matters, the idea of "kilocycles" is simpler than the forbidding aspect of the word suggests. "Kilo" means a thousand, and "cycle" means one complete alternation. The number of kilocycles indicates the number of thousands of times that the rapidly alternating current repeats its flow in either direction in the antenna in one second. The smaller the wave length in meters, the larger is the frequency in kilocycles.

The reason that kilocycles are coming into use and displacing meters is that the necessary separation of the frequency of transmitting stations to prevent interference is the same, no matter what the frequency may be. This necessary separation is variable and quite misleading when expressed in meters. Thus the number of radio messages that can be transmitted simultaneously without interference can be correctly judged from the kilocycles but not from the meters. For example, the amateurs will in the future work in a band of wave lengths from 150 to 200 meters, but this is a frequency band from 2000 to 1500 kilocycles. This is an enormously wider band when considered from the viewpoint of kilocycles than, for example, the band having the same width in meters from 1000 to 1050 meters, which is 300 to 286 kilocycles. While it is possible to carry on fifty simultaneous radio telephone communications between 150 and 200 meters, only one could be carried on between 1000 and 1050 meters.

In accordance with the recommendation of the Second National Radio Conference, the Department of Commerce and other Government departments will hereafter follow the practice of specifying in even values of kilocycles rather than meters. The conference recommended the practice of expressing wave frequency in kilocycles per second with wave length in meters in parentheses thereafter. The relation between the two is very simple. To obtain kilocycles, divide 300,000 by the number of meters; to obtain meters, divide 300,000 by the number of kilocycles. For example, 100 meters=approximately 3000 kilocycles, 300 meters=1000 kilocycles, 1000 meters=300 kilocycles, 3000 meters=100 kilocycles. The accompanying table may be used for rapid and accurate conversion either from kilocycles to meters or meters to kilocycles.

For highly accurate conversion the factor 299,820 should be used instead of 300,000. The table herewith gives accurate values of kilocycles corresponding to any number of meters and vice versa. It should be particularly noticed that the table is entirely reversible; that is, for example, 50 kilocycles is 5996 meters and also 50 meters is 5996 kilocycles. The range of the table is easily extended by shifting the decimal point.

KILOCYCLES TO METERS, OR METERS TO KILOCYCLES

New Tube Operates From a Flashlight Battery

By C. H. Huntley

A RADIO tube which is claimed to consume 70 per cent. less current than any of the small or so-called peanut variety now being sold and the first to operate with the filament current supplied from the ordinary flashlight battery, has been perfected by the General Electric Company. It will be known as the UV-199. This new type radiotron has the X-L tungsten filament. The filament wire is extremely small, being but one-fourth the diameter of an ordinary hair. This new filament is considered practically ideal. It has the high efficiency of electron production of the coated filament and the uniformity of operation and ruggedness of the tungsten filament. It has the quietness of operation of the coated filament and a lower operating temperature than the old tungsten filament. It has the long length of the coated filament and the long life of the tungsten filament.

The wattage consumed by the filament of this tube is .18, or approximately but 1/27 of the energy used in the UV-201 tube. Yet the characteristics when used in a radio set are slightly better. The filament runs at a temperature about 400 degrees cooler than the old type of radiotron tube.

This radiotron might almost be termed "the tube with nine lives" because if the filament is operated at too high a temperature the electron emission falls off and the tube becomes inoperative. However, by operation at rated voltage with the plate voltage off for a period of time normal electron emission can be regained. The length of time required to perfect this recovery is proportional to the length of time at which the tube was operated at abnormally high filament voltage. This does not mean that for uniformly satisfactory results careful adjustment of filament voltage is not essential. It does mean, however, that improper filament operation does not spoil the tube beyond recovery. This tube is an excellent radio-frequency amplifier, because the capacity between elements is lower than that of the UV-201-A tube.

Although the base is of the same general design as the standard four-prong base, it is of smaller diameter and the arrangement of the leads to the contact pins is different, the grid and plate contact pins being opposite rather than adjacent. This has been done to facilitate wiring and simplify connections in a multi-tube set.

This tube operates satisfactorily in all circuits which were used with the old UV-201 tube and should give slightly superior results, especially in radio-frequency amplification. Constant voltage operation of the filament is recommended. However, constant current operation does not entail the serious loss of life that followed constant current operation in the old tungsten filaments.

Work on the filament in the new tube has been going on in the Research Laboratory of the General Electric Company for more than eight years.

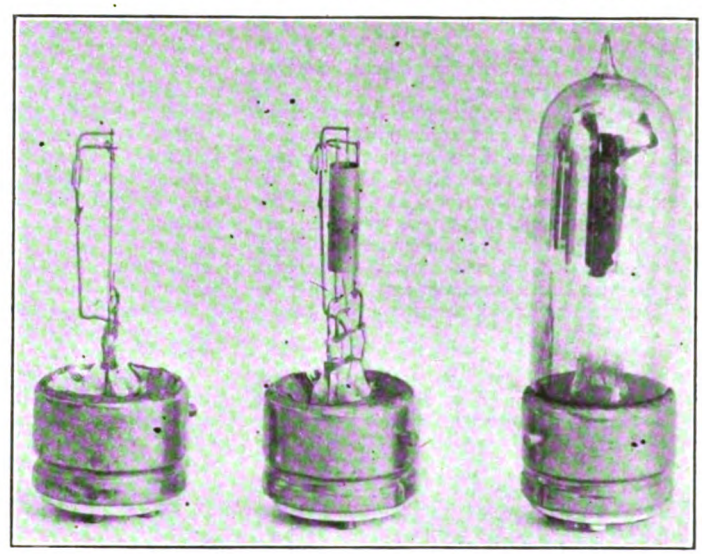
The UV-199 tube requires so little filament energy that the ordinary No. 6 dry cells give remarkably long service. For instance, three No. 6 dry cells in series will operate one of the UV-199 tubes one hour a day for a whole year. On a three-tube set three No. 6 dry cells will operate the tubes one hour per day for a period of over four months.

In the case of portable sets using three-cell flashlight batteries, it is recommended by the makers that one set of three flashlight cells be used for each tube in the set. It is immaterial whether each tube is wired separately to one of the batteries or whether they are all placed in parallel, provided separate rheostat control is made for each tube. If this is not employed for each tube and only a common rheostat provided the batteries should be connected in parallel.

In common with all receiving tubes, there are certain precautions which should be observed in order to obtain satisfactory results.

The proper grid bias must be used, depending in amount upon the plate voltage employed. Under certain conditions of small interference, slight static and weak signals, a grid leak resistance as high as six to ten megohms can be employed with success. With strong signals and heavy interference a lower grid leak resistance down to possibly two megohms should be used.

It should be understood that this UV-199 tube will not deliver the energy as an amplifier that the UV-201-A will. The UV-201-A is a remarkably powerful tube and has electron emission, mutual conductance and amplification far above any other receiving tube. It must not be expected that with a filament expenditure of only .18 watt that as powerful results can be obtained as an amplifier as with the expenditure of 1.25 watts.



Details of new and efficient tube which operates from a flashlight battery.

On account of the low filament current required by this tube it is essential to have the filament rheostat of sufficient resistance. For operation from three dry cells, the filament rheostat resistance should be at least thirty ohms per tube. If a six-volt storage battery is used, the resistance should be at least sixty ohms. In multi-tube sets the sockets for the tubes should be cushion mounted so as to minimize the effect of vibration.

With any vacuum tube, and particularly with the UV-199 tube, the changing of connections or adjustments of the wiring of the set is dangerous unless the tubes are removed from the sockets or the "B" batteries entirely disconnected. Inasmuch as many adjustments can most advantageously be made while the set is in operation, it is strongly recommended that a protective resistance be placed in one lead of the plate battery, preferably immediately next to one battery terminal. An almost ideal resistance for this purpose is a 10-watt 110-volt tungsten lamp. The UV-199 has just been placed on the market by the Radio Corporation of America.

Answers to Readers of Radio World

In regard to the reflex circuit described by Mr. C. White in RADIO WORLD *for Feb. 17, will WD-11 tubes work satisfactorily in this set? What make audio-frequency transformer will work best?—Dr. J. T. Shadburne, Butler, Mo.*

These tubes will work in the circuit you mention, but for volume would advise using a tube such as the U. V. 201 or U. V. 201A. Any good make of transformer will do. It is of the utmost importance in the construction of any set, and reflex sets especially, that only the best of material be incorporated. Cheap apparatus gives poor results.

* * *

When using the WD-11 as an amplifier is it necessary to put a protective fuse in the plate circuit? Will fuses in the phone lead prevent signals from coming through? Will they prevent the phones from burning out if I use 60 volts on my plate? Is 60 volts too much to use on these tubes?—Wm. Jackson, Charlotte, N. C.

It is not necessary to put protective fuses in the plate circuit as the current flowing is so small. Fuses in your phone leads should not stop you from hearing signals, but the fact that you are using 60 volts in the plate circuit should not cause you to put fuses in, unless you anticipate short circuiting your plate battery across the phones. These particular tubes will stand up to 100 volts on the plate without harming the tube. We do not understand why you want to use protective fuses in the plate circuit. They are used in the filament circuit to prevent the filament from burning out should you accidenly short circuit the B battery across the A battery leads.

* * *

I would like to get blue prints of several sets you have described in RADIO WORLD. *Will you kindly advise me how I may do so?—Frank H. Dunster, 32 West 98th Street, New York City.*

RADIO WORLD does not publish blue prints of sets, panel layouts or circuits, unless definitely so stated by the writer in the article. If the latter is the case, you may address a letter to him care of RADIO WORLD and it will reach him.

* * *

I have constructed the set described by Arthur S. Gordon in RADIO WORLD *for April 14 and cannot get anything outside of WEAF, although with a Reinartz hook-up using Murdon 1½ volt tubes I get WOC. What can be the trouble?—Maurice C. Eddy, 2551 Bedford Ave., Brooklyn, N. Y.*

There is no reason why if you have this set hooked up correctly you cannot get better results. This is not a new hook-up, but one that has been tested out. It is the single circuit regenerative using the rotor as a tickler. Go over your wiring very carefully, making sure of each connection. You should get as good results with this set as you do with your other. Make sure of your connections and examine your condensers and grid leak.

* * *

Can WD-11 tubes be repaired? Are there any good filament protectors on the market? —Henry Eisminger, Pulaski, Ia.

Yes, these tubes can be repaired. The best filament protectors are the small fuses, either the type that fit over the projecting lug of the tubes, or the telephone type. The last mentioned can be bought at any electrical supply store that deals in telephone parts. A good way in which to prevent trouble is to put an ordinary 60 or 75 watt electric lamp in series with the B battery leads as a ballast lamp. This will allow the B battery to operate the circuit, but will prevent the filament from burning out should your B leads accidently cross the filament circuit.

* * *

I intend using the regular three circuit regenerative circuit with three steps of audio-frequency amplification. Is this too much, or could more be used?—R. L. Halman, 22 Lawrence St., Watervliet, N. Y.

You can use three steps of audio-frequency amplification, but the distortion and noise will be so great that it will hurt the signals more than help them. With the regular three circuit regenerative set, two steps of amplifications are generally sufficient for any one's needs. It is better to employ one stage of audio and a power amplifier, to obtain volume of signals than it is to use too many steps of single amplification.

* * *

In RADIO WORLD *for Feb. 17 you published a circuit by G. W. May. How far will I be able to receive on this set, using a 150 foot antenna, 50 ft. high?—Gene Ullemeyer, 1511 Ninth Ave., Rock Island, Ill.*

It is impossible accurately to state the receiving range of any receiver, as there are too many other outside conditions upon which reception depends. However, it might be said that using a single circuit receiver of somewhat the same design, distances of 1,800 to 2,200 miles have been covered.

* * *

I recently built one of the three tube sets described by W. S. Thompson in his article entitled "Multi-tube Reflex Circuits" and had wonderful success with it until just last week, when it started in to get weaker and weaker, and finally hardly responded to the signals at all. I notice that it seems to work for a few minutes evenings, then stops, or rather slows down. I have been over the wiring and cannot find any trouble.—Jack Taylor, Jr., Winchester, Ky.

From your description it would seem that your B batteries are going dead and we advise that you put in new ones. If you are using a crystal detector, clean it with a stiff brush and carbon bi-sulphide (carbona) occasionally, as the dust lessens the efficiency of the crystal.

* * *

In RADIO WORLD *for March 17 you published a hook-up for a one-tube super-regenerative set by W. S. Thompson. It works wonderfully, but I would like to increase the volume by the addition of amplification. What apparatus would I need to do it, and where could I obtain the diagram? —L. Roon, M. Sc., 1328 Broadway, New York City.*

The easiest way in which to increase the volume of signals in this circuit will be by adding additional audio-frequency amplification. The apparatus necessary for two stages of amplification will be two transformers, two sockets and tubes, two rheostats, panel, double and single circuit jack, extra B batteries and filament batteries. The hook-up you should use was published in RADIO WORLD for March 31, page 26. You can experiment with the grid leak in this circuit as it is a super-regenerative circuit and you might use the leak to advantage in your tuning.

(*Continued from page 7*)

the end of the inductance coil and the positive terminal of the "B" batteries.

I have left the layout dimensions of the panel to the constructor, in view of the fact that there are many different types of instruments, each requiring different spacing and drilling. It is only a matter of good judgment.

The wiring of the outfit is exceedingly simple and the average amateur will have no difficulty. See the accompanying diagram.

In spite of the fact that the microphone is in the ground circuit it modulates quite well. If it should heat, remove the back part so as to allow air to pass on the diaphragm. With a little experimenting the tuning of the outfit will be found to be quite easy.

To beginners who decide to build this outfit, it might be well to mention some of Uncle Sam's requirements for radio transmitting outfits and their operators. In the first place, all operators must be licensed. These can be secured from the Radio Inspectors located at the Custom Houses in the following cities: Boston, New York, Baltimore, Savannah, New Orleans, San Francisco, Seattle, Cleveland and Chicago. Write to your nearest inspector, who will send you the necessary papers.

To obtain a license the amateur must have a fair knowledge of the code, and must be familiar with the United States laws controlling radio.

Amateurs must not transmit on a wave length greater than 200 meters. The wave length of a transmitting outfit depends upon the antenna used. After you have constructed this outfit, if you do not know the wave length of your antenna, send its measurements (length, height, etc.), to the Editor of RADIO WORLD.

The simplicity in construction, the small cost, the simplicity and efficiency in operation, the compactness and neatness in appearance of this outfit, all make me feel confident that it will meet the approval of many fans. Of course, the advanced radio man might suggest several improvements, but simplicity was the author's object in designing this outfit for the radiophone beginner.

How to Obtain Vernier Control Using a 43-Plate Condenser

By J. E. Anderson

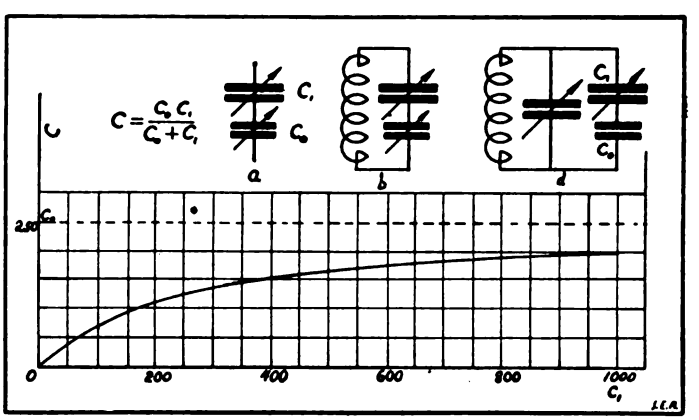
IT is not generally appreciated among amateurs and experimenters that an ordinary 23-plate or 43-plate condenser may be used as a vernier to obtain a very fine adjustment of capacity. But this may be done if two condensers are available, and the vernier action may be made extremely fine. It is based on the properties of two condensers connected in series, one of which is small in comparison with the other.

Suppose two condensers C_0 and C_1, Fig. a in the accompanying drawing, are connected in series. The capacity of this series combination as measured across the terminals is given by the product of the two divided by their sum; or expressed algebraically, $C = \frac{C_0 C_1}{C_0 + C_1}$, where C is the capacity of the two in series. The curve in the drawing shows how the value of C varies as the larger of the two is increased. In this particular curve the value of C_0 is 250 micromicrofarads. It is seen that at first the value of C increases at a fairly rapid rate, but as C_1 becomes large in comparison with C_0 there is not much change in C for large changes in the large condenser. In fact the vernier action of the large condenser may be considered to start as soon as C_1 becomes equal to C_0. The value of C is always less than the smaller of the two and approaches it assymptotically, as is shown by the dotted line in the drawing.

This property of condensers connected in series is often encountered in single circuit tuners and is erroneously attributed to broad tuning. The statement that the tuning is so broad that the signals come in all over the condenser is often heard. The trouble is that the condenser is merely a vernier and the only remedy is to increase the antenna inductance. The self capacity of the antenna is effectively in series with the tuning condenser. As long as the capacity of the tuning condenser is smaller than the self capacity of the antenna it is effective in tuning, but as soon as it becomes larger than the antenna capacity the vernier action begins and the condenser becomes useless in tuning.

A method of making use of this vernier action for fine tuning in a selective circuit is shown in Fig. b of the drawing. The series combination is connected across the tuning coil. The condenser C_0, which may have a capacity of 500 micromicrofarads, is used for approximate tuning and the larger condenser C_1 for final adjustment. First set the large condenser on division 90, or thereabouts, and tune as near as possible with the other condenser. Then the large condenser may be used as a vernier for final tuning.

A better way is shown in Fig. d. The series combination is here connected in parallel with the main tuning condenser. This arrangement is capable of extremely fine adjustment. In this case condenser C_0 may be a small fixed condenser with either air or mica dielectric, and C_1 a variable condenser many times as large as C_0 when set for maximum capacity. The smaller C_0 is in comparison with C_1 the finer the adjustment will be. For instance if the value of C_0 is 50 micromicrofarads and the maximum value of C_1 is 1000, the maximum capacity of the series combination will be 47.6 micromicrofarads, while the change



Diagrams illustrating Mr. Anderson's methods of obtaining vernier control with a 43-plate condenser.

in this due to a change of one division of the large condenser will be .013 micromicrofarad. A finer variation will hardly ever be necessary in a radio receiving circuit. If the total capacity in the tuned circuit is 500 micromicrofarads this would represent a change in the frequency to which the circuit would respond of only 9.75 cycles per second, or a change in the wavelength of only half a centimeter. If such fine adjustment is not needed the variable condenser C_1 may be made smaller or the fixed condenser larger. A good combination would be an 11-plate variable and a fixed condenser of 50 micromicrofarads capacity.

Watch Your Wave Length—The Inspector Does!

WHEN people mention casually to one another that WJZ's wave length is to be changed, they little realize that it means more than the mere turning of a switch, or increasing or decreasing of power.

When a station's wave is to be measured, there is one authority which the owner can consult. That is the radio inspector of the district. And who keeps check on the radio inspectors? Daily there is sent out from the Bureau of Standards, Washington, D. C., a series of standard waves, by which the inspectors' wave meters are accurately checked by the zero beat method. The wave meters used are of the heterodyne type and the daily checking from Washington makes absolute accuracy possible.

Now that the broadcasting stations have received reallocated wave lengths, there were many things that had to be considered. One of them was to see that the station's wave was sharp and did not slop over into the next wave length. Once the wave has been assigned and checked no deviation will be allowed, and if there is and no attention is paid to it, the station license will be revoked. Strict adherence to time schedule is also absolutely necessary.

WORLD NEWS HAPPENINGS BRIEFLY PHRASED FOR BUSY READERS

"The Radio Wave" is the name of a neat little monthly published by the Charleston, S. C., Radio Club. The editor is K. C. Parsons, who is also secretary of the club. His address is 278 King Street, Charleston, S. C.

* * *

A hit was made by the San Francisco electrical contractors recently when they staged an amateur play called "While There Is Credit There Is Hope." It was received enthusiastically—and there were radio men in the audience, too.

* * *

Radio standardization has been assigned by the American Engineering Standards Committee to the Institute of Radio Engineers and the American Institute of Electrical Engineers jointly. This is in accordance with the recommendations of the Bureau of Standards.

* * *

The Bureau of Standards has issued Circular No. 138 entitled "A Decimal Classification of Radio Subjects—an Extension of the Dewey System." The literature of radio has become so prolific that such a system of indexing seems to be a real necessity, especially for libraries.

* * *

The rate war now in progress between the cable companies and radio companies handling traffic across the Atlantic renders doubtful the consummation of the American plan for the allocation of the former German cables in the Atlantic. The situation has caused the cable companies to delay new construction.

* * *

Dr. A. S. W. Rosenbach, the noted authority, who spent $1,250,000 for rare books abroad, returned to New York recently on the White Star liner "Olympic." On the way across Dr. Rosenbach said he evoked the medium of the radio to successfully negotiate the purchase of a Gutenberg Bible from James W. Ellsworth, of New York City.

* * *

Listening in on radio is now all the rage in France, and the ranks of the devotees are growing rapidly. Recently the broadcasting stations asked their listeners to send in their names, and the census showed more than 50,000 "fans" at 12,000 receiving posts. The production of wireless sets has developed greatly and the fine equipment produced in France is gaining renown.

The Fisheries Bureau of the Government issued a broadcast last week giving wholesale market prices on fish, together with the quantity of varieties available at New York, Boston, Norfolk, Jacksonville and Chicago. Each week on Tuesday evening NAA will carry similar broadcasts between 7:45 and 8 p. m.

* * *

Hiram Percy Maxim, president of the American Radio Relay League, has arranged to send an amateur radio operator with the Arctic expedition under Donald B. McMillan, which will sail from Boothbay, Me., about the middle of June. It is expected thus to provide entertainment for the long Arctic nights and enable members of the expedition to keep in touch with their families for the greater part of the distance to the pole.

* * *

An English radio enthusiast who thinks nothing of sitting up until 4 o'clock in the morning to get American broadcasting stations reports receiving the entire program of WGY, the Schenectady, N. Y., station of the General Electric Company on four different evenings. The most remarkable feature was his reception on a single tube or valve—as the English call it—home-made receiving set. He is J. H. Brittain, and lives at Eccles, Lancashire, England.

* * *

Hakon Jorgensen, of Copenhagen, Denmark's delegate to the recent International Police Conference in New York City, proposed the universal adoption of a system under which the fingerprints left by a criminal in a New York case could be indexed, codea and broadcast by wireless to Europe; and if the criminal had ever been caught before his past record could be forwarded to the scene of his newest crime all within a day. This system has been in successful use in Denmark.

Alfred Swan, a pioneer in the incandescent lamp industry, died recently at Upper Montclair, N. J., in the eighty-eighth year of his age. He was the inventor of the brass base used on incandescent lamps. He started in the lamp industry in England after the death of his brother, Sir Joseph Swan, who contributed to the practical development of the early electric incandescent lamp. In 1886 he came to the United States, where he associated himself with the lamp industry, in which he spent the remainder of his life.

Radio and the Woman

By Crystal D. Tector

THE Schenectady broadcasting station of the General Electric Company, WGY, has been honored by a Wisconsin family. A brand new baby, according to the father, has been named after the Schenectady station. He is Wallace Gordon Yadon and he lives in Delavan, Wisconsin. M. E. Yadon, advertising manager for the Bradley Knitting Company wrote to WGY as follows: "We have a baby called the 'radio boy' because we have named this child after your station, which indicates that not only the child is a favorite but that your station is our favorite. We only hope that you will broadcast twenty-four hours daily. The boy's name is Wallace Gordon Yadon. The receiving set has been placed at the hospital for the past five weeks and even the little fellow is getting so he can recognize the announcer. We are proud of our son and trust that you will welcome what we think is your first namesake."

* * *

My cousin, whom I haven't seen in years, recently took it into her head to come to New York and knowing that we lived in the suburbs decided to come to us. She spoiled my entire day by telling us that her husband's nephew was the owner of a powerful broadcasting station and that she occasionally sang. "It is such a nuisance though, because I really enjoy the applause of my listeners, and I can not hear them when I broadcast." Well, that surely is nice. Most people are satisfied knowing that hundreds of thousands are listening to them, but even at that you can not satisfy everybody and some people are just little piggies for praise. I would simply be delighted could I even talk into "those fearful black discs" without wanting to hear any applause at all.

* * *

Babies now cry for radio. The new national pastime has invaded the nursery and many mothers are adopting radio waves as pacifiers. A mother of six children, the oldest eleven years old, writes WGY, the Schenectady broadcasting station of the General Electric Company that her youngest child, aged fourteen months, is already a fan. Mrs. Robert Barbour of Rensselaer, N. Y., says: "I wonder if it would interest you to know that I think I have the youngest radio listener. My baby is fourteen months old and she walks to the desk where I have my crystal set and points for me to open it. When there is anything she sits with the ear phones just as nice as any large person but as soon as it stops she takes off the phones and starts to scold for more. I have six children and they all like to listen. I have two sets of phones and they separate them."

DX Nite Owls Records You Can Shoot At

He Calls It a Record—How About It?

From H. S. Fredrickson, 406 Howard Street, Charles City, Ia.

I HAVE what I call a record on the total number of broadcasting stations heard, and also on the largest number heard in one night. To date I have heard one hundred and seventy-nine different broadcasting stations with my set. The number includes stations on both coasts, Canada, all through the United States, and one—"PWX"—from Cuba. As a list of calls would take too much space I will give the number of stations from each state, as follows:

Alabama, 2; Arkansas, 1; California, 7; Colorado, 7; District of Columbia, 1, Georgia, 4; Idaho, 1; Illinois, 11; Indiana, 5; Iowa, 14; Kansas, 5; Kentucky, 2; Louisiana, 3; Massachusetts, 3; Michigan, 5; Minnesota, 9; Missouri, 11; Montana, 2; Nebraska, 6; New Jersey, 2; New York, 9; North Carolina, 1; North Dakota, 2; Ohio, 9; Oklahoma, 7; Pennsylvania, 10; South Dakota, 1; Tennessee, 5; Texas, 13; Utah, 2; Virginia, 1; Washington, 1; Wisconsin, 7; Canada, 9; Cuba, 1.

On Friday, March 9, 1923, during a period of only four hours (7:15 to 11:15), I copied forty different broadcasting stations—all DX boys—as follows:

WOC, Davenport, Ia.; CFCF*, Montreal, Canada; KYW, Chicago, Ill.; CJCG, Winnipeg, Canada; WCAE, Pittsburgh, Pa.; WHB, Kansas City, Mo.; WGY, Schenectady, N. Y.; WOR, Newark, N. J.; WBAA*, Lafayette, Ind.; WDAJ, College Park, Ga.; WDAO, Dallas, Texas; WGAQ, Shreveport, La.; KDYL*, Salt Lake City, Utah; KDKA, Pittsburgh, Pa.; WPAK*, Fargo, N. D.; WIAR, Paducah, Ky.; WJZ, Newark, N. J.; WOS, Jefferson City, Mo.; WHAS, Louisville, Ky.; WFAT, Sioux Falls, S. D.; WMC, Memphis, Tenn.; WDAF, Kansas City, Mo.; CKCK, Regina, Canada; WEAB, Fort Dodge, Ia.; WSY, Birmingham, Ala.; CJNC, Winnipeg, Canada; WAAC, New Orleans, La.; KFAF, Denver, Colo.; WLAG, Minneapolis, Minn.; WGM, Atlanta, Ga.; CFAC, Calgary, Canada; KHJ, Los Angeles, Cal.; WIP, Philadelphia, Pa.; WSB, Atlanta, Ga.; KFDL*, Denver, Colo.; KLS*, San Francisco, Cal.; WBL, Anthony, Kansas; WOAZ, Belvidere, Ill.; KLX*, Oakland, Cal.; WJAM, Cedar Rapids, Ia.

*New stations.

My set is home-made—detector and two stage; ultra-audion circuit. The second stage was added only the night before I received the forty stations, so 172 of the 179 stations were heard on one stage.

From the Lone Star State

From Kent Deckard, Rusk, Texas.

I AM a constant reader of RADIO WORLD and am interested in the DX records so I am going to submit a few of mine. I purchased my set on November 2, 1922, and have received 256 different stations, including about 50 amateur stations. Some of the most distant stations are: CFCN, Calgary, Canada; PWX, Havana, Cuba; 6KW, Tuinuco, Cuba; KDKA, East Pittsburgh, Pa.; KGW, Portland, Oregon; WGY, Schenectady, N. Y.; KHJ, KFI, Los Angeles, Cal. On April 18 between 6 and 1:15 o'clock I received 34 different stations. They are as follows: WEAY, WHB WGAR, KDKA, WKY, WHAS, WBAP, WOC, WCX, KSD, WOS, WGV, WLAG, WSY, WEAH, WLW, KOB, KHJ, WMC, WPAD, WSB, KFFQ, 6KW, WRAL, WDAJ, WQAQ, WDAF, KWH, CFCN, WGM, KFI, 8XAW, 5XAJ.

I have a Tresco set with one stage of radio frequency. I work detector and amplifier on 22½ volt B battery and get better results and louder signals than if I use 45 volts for amplifier and 22½ volts for detector.

THE editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

Just to Make It a Little Harder

From Jerome M. Freedman, 1333 Iranistan Avenue, Bridgeport, Conn. Radio 1-AOE & 1-CCR

I HAVE been reading your column which you have donated to the Nite Owl gang. I have never bothered with making out reports of the stations I have heard unless it was far enough to send a Q. S. L card. But here I make my debut in the RADIO WORLD. The receiver at this station is a Reinartz tuner, and I'll say that this make of set is the rattlesnake's hips for long distance DX. It will be noticed in the hook-up that there is a choke coil in the plate

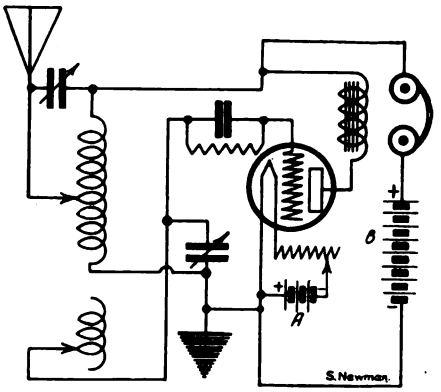

Diagram of improved Reinartz circuit as used by J. M. Freedman. The choke coil in the plate circuit is something radical in receiving circuits.

circuit. This choke is wound with about 75 turns of No. 22 B. & S. wire. Wind the coil in any zig-zag fashion and while it is on the coil tie threads of cotton in places and remove the wire from the coil. Don't be fancy when winding this coil. For audibility the wire that went to the plate switch goes to the stationary plates of the aerial condenser. Sometimes the set did not function or oscillate on 200 meters, so I found, by disconnecting the ground wire, she would then work fine. I used *detector* only to get these: 6-ZZ, Arizona; 6-XAD, St. Catalina Island, Cal.; 6-XJ, California; 6-CC, Colusa, Cal.; 7-GV, Seattle, Wash.; 7-ZU, Montana; 7-ZV, Wyoming; WHAD, WDAF, WMAQ, WEAS, KSD, KDKA, WJZ, WOR, WOS, WBT, WDAL, WDAP, WWJ, WLW (phone and code), WSB, WBAP, WHN, WFAS, WAAM, WBAM, WCAE, WEAF, WHAS, WHAV, WHAZ, CFCA, PWX, WKAQ, WGI, WGY, WGM, KYW. How about it, Eddie? Pretty good? I will answer any cards.

The Pup Drags It In on an Indoor Aerial

From Robert N. King, 77 Mayo Avenue, Needham 92 Mass.

THIS is my list of stations that I have heard. I used the Stockelberg Pup Circuit and U.V.-201-A for detector and C301-A for amplification. I used an indoor aerial: DX—WGY, WRL, WRW, WHAZ, WHAM, WGR, WEAF, WMAC, WHN, WMAK, WJZ, WOR, WIP, WOO, WFI, WNAT, WGL, WDAR, WCAU, WWAD, KDKA, WCAE, WJAS, WHAF, WRAJ, WGAL, WQAA, WLAO, WSAJ, WBAK, KYW, WDAP, WMAQ, WJAZ, WPAD, WJAX, WEAO, WCAH, WLW, WDAK, WAAQ, WEAN, WJAR, WLAK, WWJ, KOP, WHAL, WHAS, WGAM, WSB, WGM, WHAO, WBL, WOC, WFAA, KSD, WMC, WNAV, WLAG, WBAH, NOF, WEAS, PWX, 5-KW, CFCF, CKAC, CHYC, CFCA, CJGC, CFCX, WLK, WOAW, WLAN, WSY, WCAT, KFCV.

Local—WNAC, WFAU, WAAJ, WGI, WQAS, WDAU, WBZ, WCN, WMAF.

Important! Verification Wanted! Who Knows?

From Kenneth M. Jones, 1646 Richmond Avenue, Columbus, Ohio

I HAVE a few new DX records I would like to enter in your DX page. I am using one radio and one audio. The set is a Grebe RORN tuned, radio-frequency, a detector and one stage of audio-frequency.

CHB, Calgary, Canada; KGO, Alameda, Cal.; KNO, San Francisco, Cal.

On the night of March 14, 1923, between the hours of 9:45 and 9:58 p. m., I think I listened to a concert by a Brazilian orchestra and a talk by one of the officials of the Brazilian government (of course, in Spanish or Portuguese) from a station—SPC or SPE—at Rio De Janeiro, Brazil. I wrote for confirmation, but I did not get any reply at all, so I assume that my letter was never received by the right parties. This is not bad on two tubes, as no radio-frequency was being used at the time. The distance is about 5,900 miles air-line.

They Have Owls in Mexico Too

From S. A. Grogan, Apartado, Num. 106, Tampico Tampa, Mexico

I HAVE been reading some of the records of the DX "Nite Owls," and believe that my last night's listening period was worth while. My set consists of three stages of radio-frequency, detector and two steps of audio-frequency, using the ordinary regenerative circuit, rigged for using honeycomb coils, but am using a "Tunit."

WHB, Kansas City, Mo., 1,180 miles; WGY, Schenectady, N. Y., 1,990 miles; WBAP, Fort Worth, Texas, 740 miles; WFAA, Dallas, Texas, 750 miles; WMC, Memphis, Tenn., 1,000 miles; KSD, St. Louis, Mo., 1,220 miles; WSY, Birmingham, Ala., 1,030 miles; WOS, Jefferson City, Mo., 1180 miles; WLAG, Minneapolis, Minn., 1,580 miles; KFI, Los Angeles, Cal., 1,490 miles; WSB, Atlanta, Ga., 1,140 miles; KFDB, San Francisco, Cal., 1,800 miles; WDAF, Kansas City, Mo., 1,180 miles; CFCN, Calgary, Alta., Canada, 2,175 miles Total, 18,455 miles.

If any one should wish to check me up on CFCN, will state that I heard a cabaret program being broadcast between 12 midnight and 1:00 a. m. I tuned them in at 12:15 a. m., Mountain Time, and kept them on until they signed off.

Teaching the Infant Radio to Walk

By Henry Ferris, Jr.

THE growth of Radio has been bewilderingly swift. Just when Father Business was about to offer it a bottle he found to his amazement that the infant was already in long pants and yelling for roast beef. The result has been confusion in the Radio household.

In this particular discussion we are principally interested in the "kitchen" of the Radio household—that is, those phases of Radio's problems which have to do with *marketing*.

Our object is, by observation and analysis, to point out certain fundamental weaknesses of Radio merchandising as it is now being done, and, by analogy with certain lines of business which have been much longer established, to point a way by which the infant Radio can be fed the same diet without getting indigestion. In fact, the precocious infant has already had its fingers in the jam jar, and therefore it is desirable to find a prescription for the indigestion that has already set in.

Just as a physician seeks *facts* as a basis for his diagnosis, the author went out and visited all the important factors in the trade in order to make a correct diagnosis of the current situation in Radio. These factors included:

1. "Consumers"—i. e., users of Radio apparatus.
2. Jobbers and dealers—i. e., sellers of Radio apparatus.
3. Broadcasters.

The result of this investigation was that certain conditions came definitely to light, and certain conclusions were reached as to the underlying causes of these conditions.

Everybody likes to read the back of the book first, so the causes will be stated first. They are many and diverse, but the principal causes can, by careful analysis, be boiled down to these:

1. The development of broadcasting.
2. The amazing progress of invention.
3. The equally amazing adaptability of the American Radio public.
4. The educational work done by the Radio press and the big daily newspapers.
5. The avid thirst of the American public for up-to-the-second information; its deep desire for all educational and enlightening influences, and its curiously mixed love of good music and passion for "jazz."
6. The fact that all of these benefits are, after a small first investment, available, *at will*, at any hour of the day or night, and absolutely free.
7. The need for a constructive and educational hobby, an outlet for excess energies, a refuge and change for tired brains, a fascinatingly interesting excursion into the mysteries of nature.
8. The tremendous fortunes made over night by youthful inventors.
9. Legal developments relative to "wave bands," restrictions on amateur sending and the classification of broadcasting stations.

With these causes the Radio public is largely familiar. They will not be enlarged upon for the reason that it is with *effects on the trade that we are* chiefly interested.

Broadcasting has increased enormously since April 1, 1922, when 137 broadcasting stations were sending, until now, when there are over 500 licensed stations in operation and, with the exception of one point in the southwestern section of the United States, there is no spot in this broad land of ours that is farther than 150 miles from some broadcasting station. The United States Bureau of Standards is authority for this statement.

Take a population map of the United States and spot these 500 stations and you will see that today *Radio broadcasting is available* to 98 per cent of our people, *territorially*. Financially, also, it has become available to anybody who can spend as little as $15.00 for a simple, home-made set. From a merchandising viewpoint this means that small tradesmen everywhere are beginning to sell Radio apparatus. Cross-road general stores have added Radio to the multitude of things they "carry." Plumbers, tinsmiths, electricians, hardware and toy stores are installing loud-speakers in their windows or doors to draw the crowds—and *it does the trick*.

The points we are getting at are:

First, that the entire American public is becoming "Radio-conscious." The market is enormous and growing daily more complex.

Second, that Radio equipment is being sold in an unfortunately great number of instances by trade factors that are incapable of doing a good job. Ignorance, not only of the basic principles of Radio engineering, but, worse, a still deeper ignorance of the right way to conduct a retail Radio business, is resulting in a very high percentage of failures. These bankruptcies are one fertile source of the worst evil in Radio merchandising—price cutting. Bankrupt stocks sold for a song to "gyp" buyers are re-distributed at less than the cost of manufacture. Result: Manufacturers themselves "go broke" in the effort to sell to the trade against this type of competition, and then *their* inventories flood the market with disastrous results; irresponsible buyers, fly-by-night Radio "stores," unguaranteed, un-trade-marked, imperfect, out-of-date and shop-worn Radio products being sold to a "green" market—it's a true picture and a disheartening one.

What are the remedies? What medicine will cure this indigestion?

First, *education of the public*. This process is going on very rapidly, thanks to an enlightened Radio Press and the broad business knowledge of the big metropolitan daily newspapers.

Second, slowing down of the buying impulse to the point where the faculty of *judgment* rules trade and public alike.

Third, selective selling by manufacturers who will soon see the light and sacrifice immediate sales and immediate profits for the sake of a better knowledge of *just who is selling their goods* and *just how they are being sold*. The penalty for misrepresentation, price cutting or failure to give service to be a refusal to sell these outlets any more supplies. This process is going to hurt. There will be, and indeed now are, many complaints about "The Radio Trust" and the like. Most of it is pure bunk and self-deception. The big factors in the Radio industry want Radio apparatus *intelligently* sold; sold at a profit; sold under guarantees that mean something; sold with exact knowledge of the functions, capabilities and limits of each piece of apparatus; sold under a *true* representation of the result that the public may and *may not* expect from any given expenditure.

Fourth, governmental restriction and even licensing of trade-outlets. It's coming is sure as fate—watch for it.

The more or less trite aphorism, "Experience is a hard school but fools will learn in no other" is applicable to the man who thinks that, just because he has $1,500 and a taste for fooling around with electricity, that he is fully qualified to sell Radio equipment to an even more gullible public.

The public learns *faster* than the dealer. Candid dealers will tell you that their most important merchandising lessons are learned by keeping their ears—and minds—open to the comments, criticisms, complaints and comparisons that drift in every day *across the counter*.

If we were asked to give advice to dealers we might offer this: Never expect *praise* from the public—just look for *familiar faces*. If you don't see them, your house is built on sand. If you *do* see them, *serve* them if it costs a fortune, and they will bring their friends. Then you will be building on rock.

A word of warning: Don't use the mystic power of advertising for purposes of *deception*. The writer knew of a case of a dealer who, during the recent shortage of tubes, thought it would be a clever idea to advertise that he had some. He is still in the hospital, but he is quite definitely *out* of the Radio business, to its everlasting betterment. Cynical "gyps" will curl the lip of scorn at this and call to mind the number of cases where they have misrepresented goods or otherwise trangressed the laws of good merchandising and "gotten away with it." To him we say: "Watch your balance sheet!" Transient trade *never* pays the best in any line of business. You pay out every nickel of profit you make on transient trade in the form of rent. Don't think that your landlord doesn't know how many people daily pass your door—he surely does, and you pay a proportionate rental. No, it's the steady customers that pay profits—and there's only one receipt for getting them and holding them. Here it is:

Treat every customer that comes in the front door as if your sole chance of staying in business depended upon retaining his goodwill.

Carry the *right* merchandise—*standard* goods built by real Radio engineers—not *thrown* together by some ex-amateur.

Know the *whole truth* about everything you sell and *tell it* to your customers.

Try to conduct your store in accordance with good business principles. Study the methods of successful druggists, grocers, hardwaremen—and *adapt* what you learn.

Last and most important—give *service*. We're not going to define it. If you don't know what it means, you don't belong in Radio.

Don't do anything for your own benefit that will hurt Radio as a whole.

We have not meant to sermonize. We started out to paint a picture of conditions as we actually saw them and we have rushed at the job of trying to reform the world with our usual enthusiasm.

But the job is too big for any one man. And the real fact is that the situation will *eventually* work itself out on sound economic lines. The truth needs no defense! Our only excuse for this article, then, is a more or less laudable desire to speed the process. With apologies to one of the really great merchandisers of the world, it might be put: "Eventually better Radio Merchandising—Why not *NOW?*

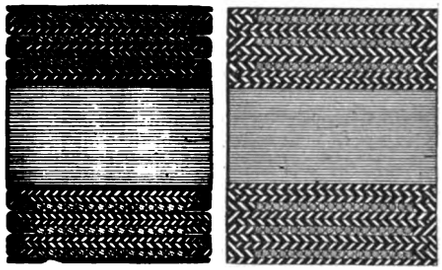
Method of Winding Electric Coils

No. 1,450,362: Patented April 3, 1923. Patentee: Philip Gilinson, Lowell, Mass.

THE object of the present invention is to overcome difficulties and to provide an electric coil which is much easier to wind, which has the spaces between successive layers of insulation substantially closed, which is much more effectively insulated than are ordinary coils, and which is generally superior. The invention comprises layers of insulation having ends of increased thickness, the ends being of sufficient thickness substantially to close the aforesaid spaces between the layers of insulation at the ends of the coil. This increased thickness is preferably produced by upturning the ends of the layers of insulation before the layers are applied to the coil, and the preferred way of upturning the ends of the layers of insulation is to fold the ends back into parallelism with the layers of insulation respectively. The layers of insulation may be made cylindrical, either circular or with flattened sides, in which case they are slipped on over the ends of the coil. However, the layers of insulation are preferably made o strips or ribbons, in which case a strip of sufficient length to encircle the coil and preferably overlap somewhat is wound upon the coil after each layer of winding has been applied. When making the insulation in the form of strips or ribbons, the edges of the ribbon are folded over before the ribbon is wound on the coil and preferably at the time the ribbon is manufactured. When the ribbon is impregnated with varnish or the like the varnishes cause the folded edges to adhere to the main portion of the ribbon. In the preferred form of the invention the insulation between the winding of the coli is made up of two parts or strips, one part being narrower than the other. The narrow



Sectional views of a coil wound by Gilinson's method.

strip is placed on the wider, the ends of the latter being folded over and upon the former. The strips of insulation may be of the same thickness or of different thicknesses. Such a construction makes a long wearing coil in which the windings are not easily displaced and the danger of sparking between the windings is eliminated.

Apparatus for and Method of Electric Current Control

No. 1,450,749: Patented April 3, 1923. Patentee: George W. Pierce, Cambridge, Mass.

THIS invention relates to an apparatus for and a method of controlling electric currents. The object of the invention is the control of a comparatively strong electric current by means of a comparatively feeble expenditure of energy, and particularly the rapid and reliable control of a periodic current furnished by a comparatively strong local source of electro-motive force by means of comparatively feeble electrical

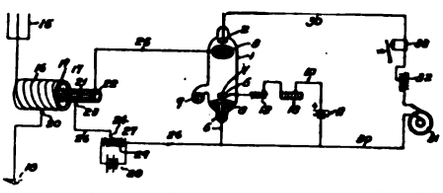


Diagram showing Pierce's method of electric current control.

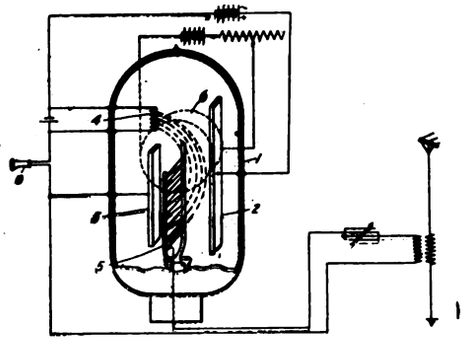
variations or impulses, or the control of a periodic current by another current or electro-motive force the character of which it is desired to alter. With the above object in view the present invention consists in the apparatus for and method of controlling electric currents hereinafter described and particularly pointed out in the claims. This invention is particularly applicable to apparatus employed for electric signalling in which it is desired to control a comparatively strong local current by means of comparatively feeble signal impulses. The present invention is, however, not limited to signalling apparatus, but may be employed wherever it is desired to effect a sensitive and reliable control of electric current where the energy available for effecting the control is comparatively feeble, or is of a character which it is desirable to transform.

Wireless Amplifier

No. 1,450,275: Patented April 3, 1923. Patentee: Chester T. Allcutt, Pittsburgh, Pa.

THIS invention relates to vacuum apparatus of the type commonly employed for the amplification of impulses in the



Diagrammatic view of Allcutt's wireless amplifier.

transmission of intelligence, having particular reference to that type of apparatus wherein the flow of charged bodies from a hot electrode to a cold electrode is under the control of a grid electrode charged in accordance with the incoming impulses, the charged bodies being permitted to traverse said grid electrode to a greater or less degree, dependent upon the potential thereof. The invention has for its object to provide apparatus of the character designated that shall be simple and reliable in operation and more sensitive than the forms of apparatus commonly employed hitherto for this purpose.

R3 Magnavox Radio The Reproducer Supreme

Make Your Receiving Set Complete

The efficiency of the Magnavox Reproducer is due to its principle of construction.

Only the Magnavox (electro-dynamic) reproducer can re-create broadcasted programs according to their original *pitch, quality* and *volume.*

Without Magnavox equipment, no Radio receiving set is complete.

Magnavox R3 Reproducer and 2 stage Power Amplifier . . . $90.00

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field $60.00

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . $35.00

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

Washington Y. M. C. A. Goes on Air

THE Washington, D. C., Y. M. C. A. has filed an application for a 50 watt Class A station with the Department of Commerce. A feature of the new transmitting set, located in the "Y" building on G Street, is that the plate voltage is derived from a 468 unit storage battery instead of the usual method of employing a direct current generator. This station will broadcast talks on religion, education and physical culture, paying especial attention to matters of interest to boys. The station has been inspected, and it is expected that a license will be issued to the Y. M. C. A. within a few days, assigning a wave length of 283 meters.

It Wasn't a "Mice" Condenser!

THE usually careful proof readers of RADIO WORLD made a slip in reading copy of the Arthur Pudlin Engineering Company's advertisement on page 30 of last week's issue. Reference was made to a "mice" condenser. This, of course, should have read "mica" condenser. The error is regretted.

Harvard Radio Laboratories Increase Their Facilities

THE Harvard Radio Laboratories, 261 Franklin street, Boston, Mass., announce that they have increased their equipment and facilities for the repair of vacuum tubes and now are in a position to make deliveries in about ten days. They have a strictly up-to-date laboratory and make a positive guarantee that owners of repaired tubes will be perfectly satisfied with the work they turn out. It also is interesting to note that they are making special prices for the summer months.

The Harvard Laboratories request RADIO WORLD to inform its readers that at present they are accepting for repair only five and six watt detector and amplifying tubes using a single tungsten wire filament.

BUENOS AIRES ARGENTINE

T. V. T. Detector Tubes

BELOW MARKET PRICE

The New Triangle Plate Tubes are gridless, and completely eliminate all rasping, howling noises caused by the vibration of the grid in all grid tubes.

They have been thoroughly tested by many of the foremost radio experts and claimed to be far superior to the fragile grid tubes in strength, durability and result.

They are scientifically made to reproduce the sound of voice or music in clear, soft, natural tones.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Service Officers Form Radio Club

THE United Service Radio Association has been formally organized at the Army and Navy Club in Washington, D. C., by a group of officers from the Army, Navy and other uniformed services of the government. This club has for its objective the education of commissioned officers in the radio art and the fostering of radio development through lectures and experiments.

A lecture course by experts on radio was planned following the first practical talk given by Maj. Gen. Geo. O. Squier of the Signal Corps, a member of the association. To date about one hundred officers have joined, including some civilian experts admitted as associate members. At the second session, Capt. J. T. Tompkins spoke on the use of radio in the Navy.

Officers of the association are Lt. Col. F. P. Jackson, Q. M. C., president; Capt. J. T. Tompkins, U. S. N., vice-president, and Capt. R. B. Connor, U. S. A., secretary.

NAA Now Broadcasts on 435 Meters

ARLINGTON NAA will broadcast Governmental information on the 435 meter wave instead of 710. This change was made in connection with the Department of Commerce's new schedule. Talks on the standard radio frequency signals being transmitted by the Bureau of Standards from time to time from WWV, will be an added feature of the Commerce Department's broadcasting schedule from NAA, Tuesday evenings between 7:45 and 8:00 p. m.

One Cure for the Re-radiation Evil

EDITOR, RADIO WORLD: The issue of RADIO WORLD for April 28 made mention of a certain apartment house with about a dozen aerials on the roof, all of which led to a regenerative set, save one. The owners of these sets, owing to the unfortunate situation the result of which is objectionable interference, must be somewhat disappointed with radio. Unfortunate this situation may be, yet with the increasing installation of regenerative outfits the situation is bound to become worse, especially in populated districts.

The broadcasting stations are certainly doing all in their power with the expenditure of large sums to perfect their apparatus to improve broadcast programs. To me, therefore, it seems unfair to spoil their efforts at the receiving end. The owner of the set is entitled to clear reception. Then he will boost radio instead of complaining about the squeals from his neighbor's set. In my opinion we must try to help the broadcaster, as he is trying to help us and thus play fair with him, with the other fellow who is "listening in" and with ourselves.

The problem of re-radiation was before me. My outfit gave the neighbors considerable trouble. Likewise in return they gave me trouble. Lately I constructed the Cockaday four-circuit tuner, and now I have no more re-radiating complaints. I am a believer in this circuit. It has volume, it gives truthful reproduction, it is exceedingly selective, and the interference is practically nothing. With two steps of audio I have found the circuit the best I have ever tried.

Any tube set can be easily converted to the Cockaday circuit and the expense would be very small. It might be well to state that WD-11 tubes give excellent results—at least I found it so.

Very truly yours,
L. E. LAMB.
1241 East Seventh St., Brooklyn, N. Y.

Solving an Aerial Problem

EDITOR, RADIO WORLD: In RADIO WORLD for April 28, 1923, there was an article, "An aerial problem to solve." My experience might be of help to many fellow fans not able to have an overhead aerial.

The fire escape proved to me a salvation, with which I received as far as WGY on one tube. My longest distance was Frank Jones, Cuba, on a 75-foot aerial and with a standard regenerative set, variocoupler, two variometers and two stages of audio-frequency. Without aerial, but using the grid variometer binding post as ground connection, I receive all local stations, and WGY, WJZ, WEAF, WOR and other local stations I receive without aerial or ground.

If you publish this I wish to hear from fellow fans who try the grid connection scheme, and I will be glad to answer any questions regarding this.

In addition I wish to express my thanks to your publication as I find it very helpful to amateur radio fans.

686 Third Ave., CHRIST FATSEAS.
New York City.

Broadcasting Announcers, Attention!

EDITOR, RADIO WORLD: In regard to the kind of material for broadcasting, I think that, in fairness to all fans, a mixed program is best.

But, in my opinion, the worst feature of broadcasting is the fault of the announcer who gets his station letters thus: "ABC." The announcer should say: "A—B—C." We hear the program and don't get the stations letters, and consequently don't know who is broadcasting.

A Cool Summer Predicted—Good News for Radio Dealers

Dr. C. G. Abbot, Eminent Heliologer, Says the Sun Won't Be as Hot as Usual This Summer

THERE is one man at least who does not think that the coming summer is to be a hot one. He is Dr. C. G. Abbot. He knows all about the sun, moon, stars and other planets. He announces that the warming qualities of the sun during the months of 1923 already passed have been from 3% to 4% less than in former years.

He predicts that in all likelihood we will have an unusually cool summer and that folks will stay indoors more than ever before during this period.

All of which, of course, is glad news for the radio dealer.

WOC Assigned New Wave Length

In accordance with the provisions made at the radio conference recently held at Washington, Station WOC, Palmer School of Chiropractic, Davenport, Iowa, has been assigned a wave length of 484 meters. The Sunday afternoon concerts from 1:45 to 2:45 will be omitted until the first Sunday in September. All other schedules will be broadcast as usual during the summer.

WHAZ to Change Wave and Hours

BEGINNING with its weekly Monday evening program May 21, radiophone station WHAZ at Rensselaer Polytechnic Institute, Troy, N. Y., will broadcast on a 380-meter wave length as assigned by the United States Department of Commerce. At present this Class B station is broadcasting on a 400 meter wave. Coincident with the change in wave length, station WHAZ will change the hour of starting its broadcast programs Monday evenings from 8.15 to 9 o'clock, Eastern Standard Time (10 o'clock, daylight saving time), in order that its programs may be broadcast without interference and completed without interruption. Heretofore this station has been restricted to the period between 8:15 and 9:30 p. m. and frequently its programs have had to be curtailed. This change to a later hour will also meet the approval of the many listeners to WHAZ programs in the Middle and Far West and Western Canada.

Features of the Program from WGY

Miss Ethel Newcomb, nationally known concert pianist and probably the best known radio pianist, will be featured on the Monday evening program of WGY, the General Electric Company station at Schenectady, N. Y., May 21. On the same program will appear William Demorest, boy soprano, and Edward Rice, violinist.

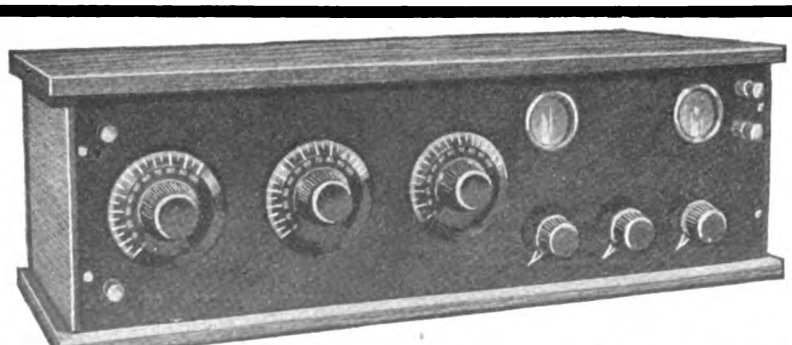
As a result of a great many requests for another evening by the Georgia Minstrel Boys, the studio manager has prepared an entirely new program for these entertainers for Tuesday night, May 22.

Wednesday night is "silent night" for WGY. Thursday evening, May 24, the WGY Players will produce the rollicking Broadhurst farce, "What Happened to Jones."

Major Edgar C. Leonard will deliver an address Friday night, May 25, on "The Citizens' Military Training Camp."

Special Licenses for Broadcasting Development

IN an effort to encourage the scientific development of broadcasting and apparatus for that purpose, the Department of Commerce has created a new form of special license known as the "Broadcasting Development Class." Licenses in this class will be issued to station owners having transmitting and receiving sets of their own design and manufacture, provided in duplicate where failure is likely to occur. These stations are to be used for the improvement of broadcasting and many special requirements are demanded by the Department. Detailed information will be given on application.



SPENCER SUPERIOR RECEIVER—PRICE $69.50

Thinks Radio Broadcasters Should Collect Royalties

A VALUED correspondent of RADIO WORLD imparts the following interesting information anent the royalty dispute between composers and broadcasters:

"I have just read your article on 'The Broadcasters - Composers - Producers Muddle' in RADIO WORLD for May 5. As the radio department of which I have charge in ———'s store is located right next to the phonograph department and also as the two departments have much in common, it has been very noticeable recently that a great many more calls for the old time records and songs have been made than for a long time. The saleswoman at the counter spoke to me about it and it occurred to me that this new demand might be the result of the fact that a local broadcasting station has been using lately nothing but old time melodies.

"If this is the case, it shows that radio has taken a decided grip on the advertising end of music. Personally, I believe this is so. I cannot understand why any fee should be paid to the composers—it should be vice versa."

State Control of Radio in Denmark Proposed

STATE control of radio telephony in Denmark is provided in a bill recently introduced in the Danish Rigsdag by the Minister of Traffic, Assistant Trade Commissioner H. Sorenson reports. It is proposed that the Minister of Public Works shall be authorized to grant concessions for installation of radio receiving sets and that the provisions of the law of April 19, 1907, concerning wireless telegraphy, shall also apply to wireless telephony. It is said that on account of the restricted wave band that will be assigned to Denmark under agreement with the Norwegian and Swedish Telegraph Services the Danish Government will exercise full control over transmitting stations.

British Radio Codes Stolen

Seven secret wireless code books have mysteriously disappeared from the British War Office. A flying squadron of secret service men has been sent into the foreign districts in an effort to apprehend the thieves. Meantime an entirely new official code is being drawn up.

A Five Year Guarantee

ARTHUR PUDLIN'S VARIABLE HIGH RESISTANCE LEAK

Eliminate the hissing and all disagreeable noises and enables you to hear all stations within 3000 miles.

We will at any time within a period of 5 years replace free of charge any A.P.V.H.R.L. that does not work satisfactorily.

Instruction By Radio from a Central "Professor's College"

THE class that ran by itself" is the new name of the class in international law at Princeton, says the New York *Times*. A tardy professor gave it the opportunity, and the campus has given it the name. A few days ago the senior class in this course assembled at the regular time and place but found no instructor. After waiting the customary five minutes one member suggested the ordinary proceeding of departing. He was voted down, and the class decided to conduct its exercises itself.

When the professor arrived he found things progressing so smoothly that he dropped down into a back seat and "listened in" for the remainder of the hour. The class has "run itself" twice since the accidental inauguration of the system.

This incident is heralded on the Princeton campus as the forerunner of Princeton's system of "self-education," which starts next Fall with the two upper classes.

In commenting on it, Professor Philip Marshall Brown said: "If this custom spreads, colleges will become non-professorial institutions. Then we would probably see a centrally located 'professors' college' where lectures by the country's best authorities would be sent out by radio and questions proposed and answered by wireless telephone. This would also wipe out the always pressing problem of teachers' salaries."

Radio Will Herald Kiwanis Convention

THE coming international Kiwanis convention in Atlanta, Ga., May 28-31, will be heralded in advance by several especially fine entertainments broadcast by the Atlanta Kiwanis Club from WSB, The Atlanta Journal station.

Several thousand leading business and professional men from every State in the Union and Canadian provinces, who will assemble in the Georgia capital for the annual meeting, will get advance tips on the hospitality awaiting them through the radio concerts, which will include some of the outstanding entertainment features planned for the Kiwanis conclave. More than 1,000 clubs, with 100,000 members, will be officially invited to listen in.

Tune in to
WDAP
—the powerful broadcasting station at
The DRAKE
Lake Shore Drive and Upper Michigan Avenue, Chicago
From Porto Rico to lonely ranches in Alberta and Saskatchewan, from sunny San Diego to Quebec, and even a thousand miles out in the Atlantic and Pacific Oceans, programs from THE DRAKE are picked up. You'll be particularly well repaid by tuning in Tuesday, Thursday, Saturday, and Sunday evenings—concerts include selections by THE DRAKE Ensemble Orchestra.
WDAP Station is but a single interesting feature of THE DRAKE, Chicago's finest hotel. When in Chicago be sure to stop at THE DRAKE. See how concerts are broadcasted, and enjoy the world famous service and surroundings of this wonderful hotel. Information on request.

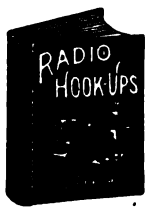
IF YOU ARE INTERESTED IN RADIO YOU NEED THESE BOOKS

Radio Books for the Expert and Amateur

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Radio Hook-Ups

By M. B. SLEEPER

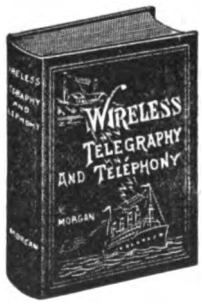
A book that gives you not only clear diagrams for all kinds of telephone and telegraph receiving and transmitting sets, but simple descriptions of each circuit shown and spaces for notes of results obtained.

PRICE 75c.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

There is a peculiar fascination about receiving radio messages from the high-power stations of England, France, Germany, Russia and Italy, as well as those located in the Pacific Ocean and the Oriental countries. Several types of simple receiving sets for this purpose are described, with detectors and amplifiers to accompany them. Suggestions are also given for operating relays and reproducing the signals on a phonograph. Schedules of operating time for high-powered stations are given. In addition, there is some valuable data on home-made wavemeters for testing and experimenting .....PRICE 75c.



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50

Design Data for Radio Transmitters and Receivers

By M. B. SLEEPER

The only book that gives tables and data for designing, receiving and transmitting apparatus so that you need no knowledge of mathematics. It's the first book a beginner buys after he has learned the use of his phone receiver.....PRICE 75c.

Construction of Radiophone and Telegraph Receivers for Beginners

By M. B. SLEEPER

The man who wants to feel the real thrill of accomplishment, and who is not satisfied in the merely making use of what others have done for him, builds his own radio apparatus. Radio men can follow the data in "Radio Phone and Telegraph Receivers" with full confidence, because each piece of apparatus described was first made, tested and found efficient before the final design was accepted. Special receivers, both crystal and audion, are shown in detail. Regenerative circuits as well as audio and radio frequency amplifiers are described with clear photos, diagrams, and working drawings prepared especially for the novice and the man who wants to receive the radio telephone broadcast. A special feature is the phonograph type radio set and the loud speaker. Fully illustrated.....PRICE 75c.

The Radio Experimenter's Handbook

By M. B. SLEEPER

Throughout the preparation of this book, one purpose was kept in mind—Answer the Practical Questions of the "Novice," of the "Beginner," and the more advanced "Student." This book will help in the selection or construction of simple apparatus for the transmission and reception of radio telegraph and telephone signals. In the chapters on radio receivers the simplest crystal, the simple audion, and the regenerative types are described in quite some detail. The question of antennas, both for transmitting and receiving, are taken up. A good many helpful suggestions are given which will be of considerable aid to the experimenter. 16 chapters. Fully illustrated.

PRICE $1.00

The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

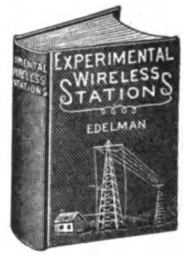
Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

How to Make Commercial Type Radio Apparatus

By M. B. SLEEPER

This book describes in detail many commercial types of spark and vacuum tube telephone transmitting and telegraph and phone receiving equipment of all kinds. The experimenter will be able to get a world of ideas for the design and construction of his next piece of radio equipment from the very clear descriptions and the 98 clearly illustrated figures.....PRICE 75c.



Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations.....PRICE $3.00

Any of These Books Sent Prepaid on Receipt of Price

Genuine

What IS Genuine Orange Pekoe?

IT has nothing to do with oranges. "Orange Pekoe" is simply an oriental term to denote one of the different gradings of tea. And here is the point you should keep in mind when you buy Orange Pekoe Tea—there are three distinct gradings:

Flowery Orange Pekoe (tea of very finest quality)
Broken Orange Pekoe (tea of very choice quality)
Orange Pekoe (tea of average quality)

The first two grades are very much superior to ordinary Orange Pekoe. Ridgways *Genuine* Orange Pekoe is the finest tea procurable, because it is composed *only of the Flowery and Broken Orange Pekoes.*

Some teas marked "Orange Pekoe" have a very small proportion of Orange Pekoe. Right there is the value in getting *Genuine* Orange Pekoe.

The way to make sure of Genuine Orange Pekoe, without any doubt about it, is to insist firmly upon Ridgways *Genuine* Orange Pekoe. Then you are certain to enjoy the superb flavor, the exquisite bouquet you should rightfully expect in this superior tea. Order definitely by name and insist upon getting it. Ridgways GOLD LABEL *Genuine* Orange Pekoe.

Not an adaptation of old methods of current control but distinctly designed to utilize the great tuning possibilities of the vacuum tube itself.

The Filament Control — *of Infinite Adjustment*

FIL-KO-STAT

enables you to hear stations you've never heard before—

Your receiving set is probably bringing in stations you never hear! You just get that faint mouse-like whistle. But you can't bring in the music because your rheostat does not properly control your filament action.

Then again, you hear stations that sound as though they were down a deep well. They come in weak and indistinct. Your tuning apparatus gets the wave length, but your wire rheostat or other so-called filament control *can't* do the rest of the job which is to adjust the electronic flow in the vacuum tube to meet the conditions under which the station is operating.

With the Fil-Ko-Stat you bring in the weak stations strong and clear.

The Fil-Ko-Stat permits you to select other stations on similar wave lengths, tune one in and the other out with a slight turn of the knob without otherwise changing any of the tuning units.

The Fil-Ko-Stat cuts out "frying." It is non-microphonic and operates silently.

The Fil-Ko-Stat regulates filament heat and gives absolute control of electronic flow, permitting the finest tuning possible. Its fine adjustment starts where the tube begins to function.

The Fil-Ko-Stat's perfect and gradual increase of filament heat insures longer life to your tubes.

The Fil-Ko-Stat is the only instrument which permits that accurate control of "A" battery current necessary in using UV 199's and other dry cell tubes.

By Test the Best

Laboratory tests prove the Fil-Ko-Stat to have a fine adjustment area (which means ability to control filament heat and electronic flow) eighteen times greater than that of the wire rheostat and several times that of the next best filament control.

For All Tubes

The Fil-Ko-Stat is regulated at the factory to the ideal "off" point for all tubes, obviating the necessity of tampering with any screws or adjustments. And the "off" position is definite. When filament extinguishes the "A" Battery is positively disconnected.

No Discs to Break

Nothing to chip. Resistance element so finely divided further division is impossible.

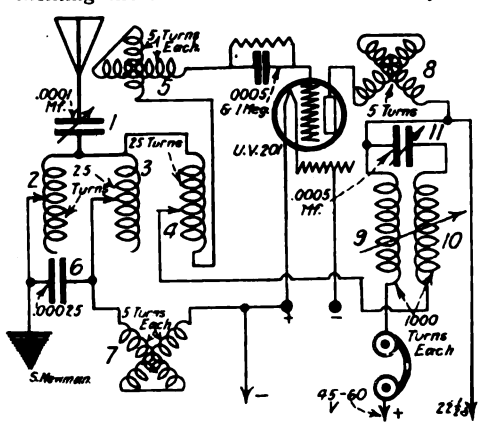
Here's One for You to Try Out—2,000 Miles on One Tube

From Leslie Libby, Vilanhaven, Maine Box 407.

AS a reader of your valuable little paper, and also as an ardent Ham, I feel that a little data on a receiver that has given me good results will help out my brother fans, as well as given them something to "Shoot at some records" with.

The hook-up below gives the idea of the set and I have found that the set works both when on my panel, and when I have the parts laying around on the table, experimenting most folks call it. I call it "just



Kind of complicated to tune—but think of the DX after it is hitting on all six?

foolin'." I have worked all the powerful stations up to 2,000 miles with one U. V. 200 tube with about 60 volts on the plate.

I have carefully marked all the parts so that there wouldn't be any mistake made. The three coils in the primary circuit are all wound on a 3-inch tube, and I have arranged them on a board all about 1½ or two inches apart. The two 1,000 turn coils are honeycombs with the coupling variable. The coupling is fixed between the other three coils. The variometer in the grid circuit is not absolutely necessary but both the variometers in the plate and filament coupling circuit are.

I will be glad to help anyone that constructs this set, and will soon send in a complete list of all the calls that I have heard. Up to the present time I have been so busy copying them that I have not had time to try to list them.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

Fully Illustrated. Price 75 Cents

IN addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

How the Modern High Power Vacuum Tube Is Made

By W. S. Thompson, E.E.

BEFORE the development of the high power tube, large transmitting stations where vacuum tubes were used to generate the high frequency oscillations were forced to connect the lower power tubes in parallel to take care of the large amount of power necessary to get a large antenna radiation. This method was not very satisfactory because vacuum tubes, when connected in parallel, generate not only the high frequency oscillations which are needed, but also generate so-called inter-tube oscillations. That is, there are present in the circuits between the tubes very high frequency oscillations which are detrimental to the efficient functioning of the set. These inter-tube oscillations became such a menace when a great many tubes were used that it was almost impossible to get

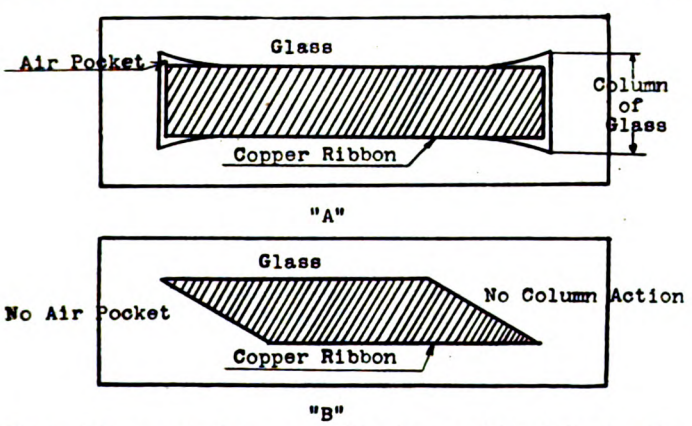

Fig. 1. Diagrams showing unsuccessful and successful methods of sealing a copper ribbon in glass.

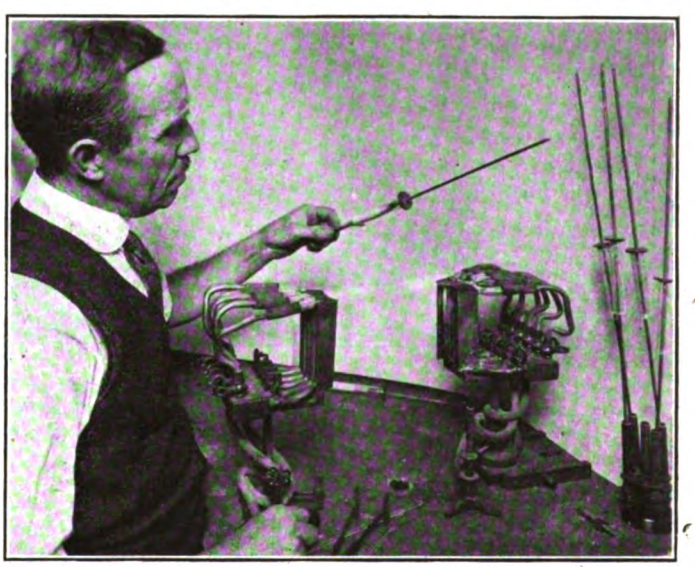
a set to operate efficiently. The natural answer to this problem was to build vacuum tubes which would handle a large amount of power so that only a few tubes would be necessary for the largest of stations.

The limiting factor in the manufacture of large tubes has been the problem of dissipating the heat generated inside the tube. The plate in the triode tube must remain cold or at least must be prevented from getting hot in order that the tube function properly, because a hot plate will emit gas which would prevent the tube from operating. The plate therefore, must dissipate sufficient heat so that it does not get hot enough to emit gas. The bright, shiny nickel plate that is usually seen in a vacuum tube will radiate only two watts per square inch of plate surface so this type of plate was discarded as impossible for a large tube.

The next attempt was to blacken the surface of the plate, for a black surface, such as lamp-black will radiate as much as thirty times the amount of heat that can be radiated by polished silver. Plates were made using a blackened plate which would radiate about nine watts per square inch of surface. To make use of this type of plate, the plate surface had to be so great that it was impracticable for very large tubes. The largest tube of this type radiated two hundred and fifty watts from its plate. The solution found for the problem of heat radiation was the water cooled tube, where



(C. Western Electric Co.)

Fig. 2. Assembling a copper disk seal to be used in a high-power vacuum tube.

the plate forms part of the outside of the tube and can be cooled by water circulation. By this method as much as fourteen hundred watts per square inch can be dissipated.

The greatest difficulty to overcome in the development of a water cooled tube was the problem of sealing the glass part of the tube to the metal part. The lower part of the tube is a copper cylinder which serves as the plate or anode of the tube. The filament and grid are mounted inside this copper cylinder and are supported by the glass upper part. A copper-glass seal must be made between the plate and the glass and also between the filament and the grid leads in the upper part of the tube.

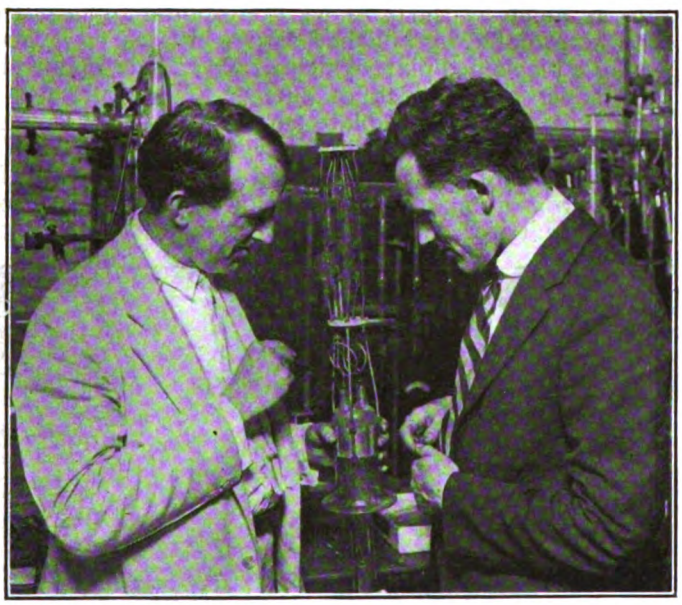
Up to the present time platinum has been considered

(Continued on next page)

Digitized by Google

(*Continued from preceding page*)

the only metal which can be sealed in glass. The explanation offered has been that platinum and glass, having nearly the same coefficient of expansion, did not separate upon cooling. For this reason platinum has been used for a great many years whenever a metal had to be sealed into a glass tube of any kind such as for the modern incandescent light and the vacuum tube. In the Bell System laboratories of the Western Electric Company a great deal of experimenting was carried on, trying to develop a means of sealing base metals to glass, the high cost of platinum making it impracticable to use this metal in large quantities. The starting point was the discovery of W. G. Housekeeper, of those laboratories that a piece of copper wire if flattened in one spot by a hammer blow would seal very well in glass using borax as a flux. The flat part of the wire sealed well, but the round part in contracting during cooling pulled away from the glass. This led to experimenting with copper ribbon and it was discovered that the seal was perfect with any width of ribbon as long as the edges of the ribbon were sharpened. The next step was sealing without the use of borax or any flux and it was found that a flux was not necessary.

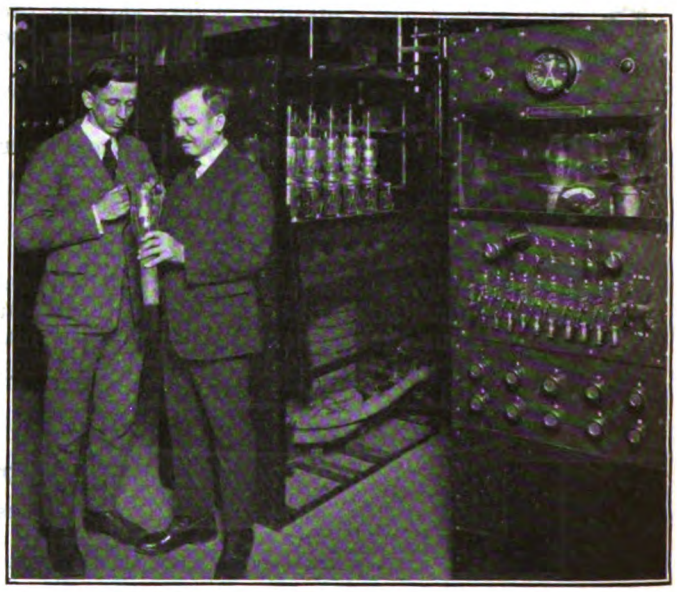


(C. Western Electric Co.)

Fig. 3. W. G. Housekeeper (left) and Dr. W. Wilson (right), of Bell System Laboratories, examining the filament—grid assembly of a 100,000 watt water-cooled tube. Mr. Housekeeper is pointing to a copper disc seal which he developed.

Experiments with copper ribbon lead to the belief that it was a column action of the glass that caused seals with thick ribbon to fail. This is shown in Fig. 1 where "A" represents the way the seal will fail if the ribbon is too thick and "B" represents the shape of the edge to avoid the column action of the glass. All the experiments seem to show that if the seals were so made as to avoid column action and if the copper were thin enough the seal would be perfect. The explanation of why the seal holds is that if the glass wets the copper it will hold it so that it cannot contract enough to pull away from the glass. The author has seen a piece of glass sealed on each side of a copper penny, the glass holding the penny so that it could not contract radially but contracted axially. A seal similar to this is made use of in the assembling of the power tube where the lead-in wires for the grid and filament enter the tube. A thin copper disk is soldered to lead-in wire and this copper disc is sealed to the end of a glass, glass being applied to both faces of the copper disc.

The other important seal, that between the copper anode and the glass tube is made by sealing the glass to the upper edge of the cylinder, having made this edge very thin so that the glass will keep the copper from contracting. The copper part of all these seals is really kept under tension by the glass, the only contracting of the copper being along an axis which will not affect the seal. The glass used in manufacturing these tubes is lead glass but from experiments which have been carried on, it has been concluded that any kind of glass can be sealed to any kind of metal providing the metal is thin enough so the glass will be able to hold it under tension. In making the seals the copper is first cleaned and given an evacuating treatment in a vacuum oven where the temperature is kept at about nine hundred degrees Centigrade. This oven is evacuated and the heating process drives all the air out of the copper saving considerable time in pumping out the completed tube. The copper and glass are then heated to a temperature very nearly as high as the melting point of copper. The glass is firmly pressed against the copper, care being taken to prevent the formation of air bubbles between the copper and the glass.



(C. Western Electric Co.)

Fig. 4. J. C. Schelleng and A. A. Oswald, Bell System engineers, examining a 10,000 watt tube of the type used for trans-Atlantic telephone experiments. Behind them are two groups of ten tubes each which furnish the power for the experiments.

In constructing the grid molybdenum is used for the grid wires and for the supporting structure. It has been found that if the grid wires were welded to their supports, the joints would be brittle, so all these joints are mechanically made by tying the wires together. The grid lead passes the filament lead in the evacuated part of the tube because it has been found that otherwise a corona discharge would be formed.

The pump used to evacuate these tubes will bring the air content down to a pressure of one hundred thousandth of a millimeter of mercury, which means that for every seventy-six million parts of vacuum there will be one part of air. The method of measuring pressure inside the tube is entirely electrical and is due to Dr. O. E. Buckley of the Western Electric Company. A low voltage source is connected in series with a low reading ammeter in the plate circuit of an auxiliary tube, the minus terminal of the plate battery being connected to the plate. A source of high voltage is connected in the grid circuit with the positive terminal to the grid, thereby making the grid positive with respect to the

A Simple Set to Take Away On Your Vacation

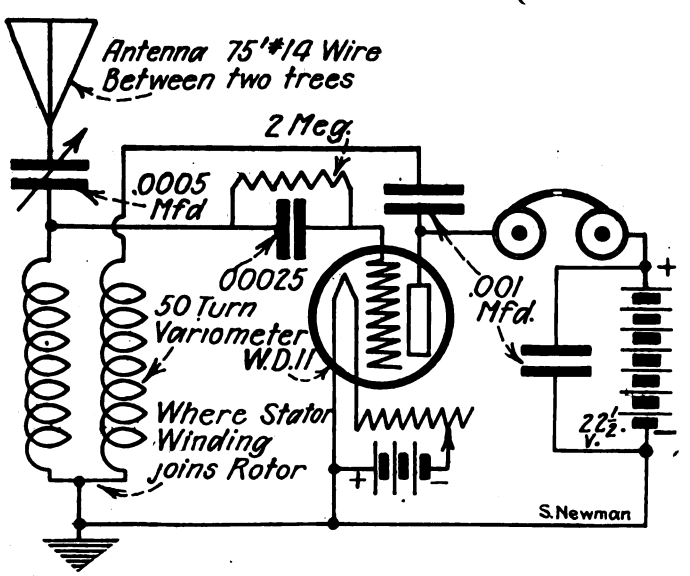
By A. D. Turnbull

FOR the real DX fan nothing will do except super-selectivity and ability to bring them in and lay them down, much the same as the negro in the woodshed when "thay's gonna be chickun on de table."

The little circuit described below, while not a new one in any manner, incorporates several new ideas that will pay the fellows to investigate. With this circuit and the air fairly clear of disturbance, the distance almost knocks at the door begging to be let in, and you have to lock the windows to keep from being smothered.

Of course a lot of you fellows will say that sort of talk is old stuff, and that you have heard it so often that you don't even get a thrill out of it. Well, don't pay any attention to it then, and just try out the circuit, which is all that you need to do, and you will wonder where the circuit has been hiding before.

First of all get yourself a good variometer, with 25 turns of wire on the rotor and a like amount on the stator. In most variometers they use the bearing or post that runs through as a shaft, as a means of connecting the two coils together. Just take a tap off of that lead, and go ahead and hook it up as shown in the diagram herewith.



Mr. Turnbull's new circuit which permits the construction of a simple set with but two controls, yet which will satisfy the seekers of super-selectivity.

When tuning in this circuit it will be noticed that there is a decided tendency of the tube to oscillate violently as the tube is turned past a certain point and the rotor of the variometer brought around to minimum. When this occurs, turn down your filament a bit, loosen the coupling and just bring them in to the delight of everyone. The tuning of this set is so decidedly easy that it is simplicity itself, as the main wave length control is the condenser. If you desire to listen in to 400 meters, set your condenser, and then do the rest of your tuning with the variometer. The direct coupling, through the condenser in the plate circuit, gives capacity coupling which, while not the most efficient means of getting feedback, or regeneration, certainly makes this little circuit bring them in.

In the construction of any single circuit sets, because of their ability to oscillate, it is very hard to operate them so that they do not cause interference with other nearby sensitive sets. I have experimented with many of them, and have found out that you really do not need to have your set oscillating to receive signals strongly. The loudest signals are always received just before the tube spills over or oscillates. This is the most efficient point, and will prevent the other receivers from being heterodyned by your receiver. With this circuit, if it is allowed to oscillate, it will cause lots of trouble with your neighbors, but by not burning your filament up bright, and always keeping the tube just inside the oscillating point, the highest regeneration will ensue and the loudest signals will be received.

If care is taken in the construction of this set, the entire receiver, batteries and all, can be accommodated in one of the smaller suitcases, such as they sell to pack lunches in. Use a neat wood or hard rubber panel and you never need be away without your set.

When you go away, use a bare wire for a ground. Throw it in the stream, stick it in the moist earth, or drive it into a live tree by means of a spike. For the aerial, I have had wonderful success by flying a small kite with a thin piece of wire woven in among the cord, and letting the kite up to 100 or 150 feet. If you can't do that, throw an insulated wire over one end of a tree and let the other end run to your set.

(*Concluded from preceding page*)

filament. The filament is then lighted so that electrons will be sent out to the grid, ionizing any air that is in the tube. As the air is ionized the positive ions will be attracted to the plate causing a current to flow in the plate circuit which is proportional to the amount of air in the tube. As long as any current flows in the plate circuit there is air in the tube. The smallest scale division on this ammeter reads a pressure of one one hundredth thousandth of a millimeter of mercury, so by reading the ammeter the amount of air in the tube can be determined in millimeters of mercury.

The testing of these tubes is accomplished by forcing them to oscillate, using a plate potential of about twelve thousand volts obtained by rectifying sixty cycle alternating current. The efficiency varies with the adjustments of the circuit and tube and may be higher than eighty per cent. when all the circuits are carefully designed and balanced. However, this efficiency is exceptional for the adjustments are very difficult to make.

The materials used for the construction were selected after considerable experimenting. Copper was used for the plate because it is very malleable and is not porous until its temperature reaches about six hundred degrees Centigrade. Steel was tried but proved to be too porous at low temperatures so it was discarded as unsuitable.

While the operation of vacuum tubes in parallel presents certain difficulties due to inter-tube oscillations, it must not be inferred that these difficulties are insuperable. Indeed, in the recent successful transatlantic telephone tests, carried out in co-operation by the American Telephone and Telegraph Company and the Radio Corporation of America, in which several speakers in New York talked to an audience in London, England, the power was supplied to the antenna from a bank of twenty water-cooled tubes operated in parallel. These tubes were of 10,000 watts output.

Thirty-four Class B Stations, each with a territorial zone, have been licensed by the Department of Commerce and began operating on May 15th.

The zone waves originally designated for Seattle and Portland have been transferred; Seattle has been assigned the 455 meter wave or 660 kilocycles, and Portland, 492 meters, or 610 k/c.

A special wave for Class B Stations in Madison, Wis., and vicinity may be designated as 345 meters if a station qualifies.

The calls and waves for 34 Class B Stations follow:

"Broadcast Central," New Super-Radio Station in New York City Dedicated to the Public

"Good evening, Radio Audience, this is WJY, the new station of the Radio Corporation of America, at Aeolian Hall, West 42nd street, New York...." With these words was "Broadcast Central" located atop Aeolian Hall, officially opened to the public at 8:15 on the evening of May 14. The Radio Corporation was enabled through the kind offices of the Second District Radio Inspector, Arthur Batcheller, to officially dedicate this monstrous and wonderful achievement of broadcasting to its place in the hearts of the thousands of listeners. This impressive ceremony, which officially opened the station, was attended by a group of the foremost men in the radio world, a gathering of the very cream of the scientific world, who attended this

"house warming party" of the Radio Corporation's new station which will reach out and make happy the hearts of millions of listeners.

The opening speech was delivered by Owen D. Young, chairman of the board of the General Electric Company. He spoke on the tremendous achievement that this opening of the Radio Broadcast Central constituted. He was followed by Major General James G. Harbord, president of the Radio Corporation, who officially dedicated the station to the public service. He said in part: "It is with this thought in mind that I dedicate 'Broadcast Central' to the people of America. I dedicate it with the belief that, in a sense this station represents the world's first national theatre, for now this great metropolis is able to annihilate distance and offer its best talent simultaneously to all parts of the country from the Atlantic to the Pacific Coast—talent that will appeal to the serious minded as well as the gay and light hearted."

Upon the termination of his speech, Dr. Alfred Goldsmith was introduced to the unseen multitudes. He spoke of the many wonders that he had witnessed in the newest of arts and sciences, and of the monstrous work that they had accomplished in making New York City the center of broadcasting. In brief he stated:

"The work of the engineers at 'Broadcast Central' is not completed. It will never be completed. Not only must the standard of the stations be maintained constantly but it must be continually improved. It is the

How Radio May Unite the Languages of Europe

By Arthur G. Shirt

SUPPOSE—just suppose—that when you light up the tubes in your radiophone some evening, instead of the usual well-known voices of your favorite announcers, you should hear some strange voice spluttering away in Greek, Persian, Turkish, Italian, Spanish, French, Portuguese, or in any one of the many tongues of the continent of Europe? What would you think? Oh, well, you say, that supposition is so remote that it is useless to even consider it. But what would you do if it wasn't a remote supposition, but a painful fact, as it is, or will be, with the radio amateur in central Europe? Although he may have a veritable host of broadcasting stations to choose from, only one or two will be taking in the language he understands. The interference will be something appalling, with a Tower of Babel effect that will do more toward wrecking the popularity of the radio in Europe than a series of earthquakes.

Makes us laugh, here in America, doesn't it? But it has been calmly estimated by various radio authorities that in five years there will be one million radio outfits in the United States capable of receiving speech from Europe, Latin America and the Orient! You may very well be the owner of one of these stations. For the sake of our argument, let us suppose that the European stations came in too loudly to be ignored altogether, and transmit such important speeches on world affairs, economic relations and such that we really want to hear them. Now how about it? Shall we hire an interpreter to translate what comes to us over the ocean by way of the air, or shall we, at the present moment, clamor for a "radio universal language," which will do for the radio telephone what the code does for the radio telegraph?

When the map of Europe and Asia is dotted with radiophone stations, as the map of America is now, will England shout Anglicisms into Persian ears, or will she use a tongue that is not only common to both England and Persia, but to every nation in between who cares to "listen in"? When China and Japan "open up" to address us, will we sign off in disgust, or will we, for once, understand with clear interpretative powers what proceeds from the mouth of the Orient?

Already one broadcasting station has felt the pressure of conflicting languages. CKAC, the most powerful station in Canada, situated at Montreal, transmits in both English and French. The problem of serving different nationalities is easily solved in this particular case, but if CKAC were situated in Switzerland, for example, would it transmit in practically all the known languages of the globe? Very likely not. It would feel the need of and eventually discover a radio language that would be intelligible to each and every one of its vast and widely scattered audience.

What will such a language be like? How will it sound and who will teach it? Why not adopt English as the language of the air? Now, you English-speaking people, test yourselves. Why not French? All these questions have been asked before, but not in connection with radio. For the subject of a world language is almost 300 years old.

The language meeting the requirements should be modern, simple and flexible and readable to a large extent at a glance by any one speaking French, English, Italian, Spanish, German or Russian. At the same time, it must not be impossible to inhabitants of China, India, Japan, or Turkey, who have difficult languages of their own. It should be brief, clear, full but not redundant, and suitable for the needs of travel, commerce, labor and polite intercourse as well as for radio communication. Moreover, so that it may not undo its own purpose by promoting international jealousy, it must be strictly neutral. That is to say, while it may draw from all languages, it must be partial to none.

To be neutral, a language must be artificial. Yet in being artificial, it must not be disagreeable to the ear. Neither must it pretend to take the place of or supplant a native tongue. It should be solely an auxiliary language, adopted for the common expediency of the whole world and for the benefit of that vast army of radiophone listeners, who, when they give their attention to a station, want to know what it is talking about.

All these qualifications sum up into quite a big bill, but there are three artificial languages in existence today which fill it more or less satisfactorily. They are Esperanto, Ido and Idiom Neutral. And in the light of present day radiophone development, it is not at all unlikely that one of these three will be chosen as the language in which the radiophone of the future will speak.

More Standard Waves for Calibrating Sets

WWV at the Bureau of Standards, Washington, D. C., will again transmit radio signals of standard frequency on the nights of May 29 and June 4 and 11, for calibrating wave meter and adjusting receiving and transmitting apparatus. Detailed information on methods of standardizing sets is available in Circular Letter 92 which may be obtained upon application to the Bureau at Washington.

The schedule includes the transmission of the following wave lengths starting at 11 P. M. Eastern Time each night and continuing until 12:41 A. M.:

	May 29	June 4	June 11
Kilocycles	1400	900	400
Meters	(214)	(333)	(750)
Kilocycles	1500	1000	500
Meters	(200)	(300)	(600)
Kilocycles	1600	1100	600
Meters	(187)	(273)	(500)
Kilocycles	1700	1200	700
Meters	(176)	(250)	(428)
Kilocycles	1800	1300	800
Meters	(167)	(231)	(375)
Kilocycles	1900	1400	900
Meters	(158)	(214)	(333)
Kilocycles	2000	1500	1000
Meters	(150)	(200)	(300)

A Single Tube Reflex of Great Selectivity

By W. S. Thompson

[The author informs us that he has received hundreds of letters from radio fans complaining of the lack of selectivity in the one-tube reflex set. He therefore has prepared the following article as a solution of this problem. He states that the set here described is the most selective non-regenerative set he has ever used which does not make use of a multitude of controls.—EDITOR, RADIO WORLD.]

THE modern receiving set should be selective above all other requirements, for no matter where a set may be located, there will be interference of some kind which must be tuned out before any desired signal can be received, with any degree of success. Another advantage of the highly selective receiving set is that it will be less affected by summer atmospherics.

The regenerative receiver has an advantage over the non-regenerative in this respect, for regeneration in itself makes the set selective to a high degree. Therefore, the non-regenerative set must incorporate some other means of acquiring the selectivity which it does not have due to feed back action. The reflex circuits have become popular almost over night, so today they are, the writer believes, the most popular of the non-regenerative sets. They have many advantages over a great many of the other sets, but to compete with the feed back circuits, they must be very selective. The worst offender along these lines is the single tube reflex, which, however, can be so designed that even this disadvantage can be overcome.

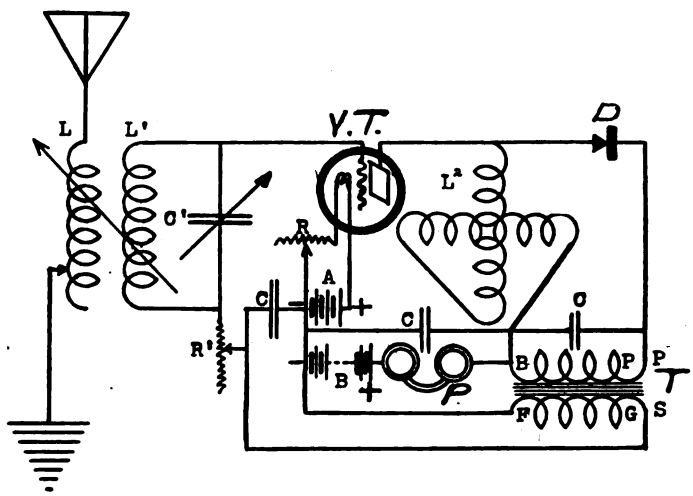
The hook-up shown in the diagram herewith is for a one tube reflex which will enable any user to tune out almost any interference and will eliminate atmospherics to a great extent if properly handled. The parts used are given below and lettered corresponding to the lettering in the diagram.

L —Tapped primary of a vario-coupler.
L'—Secondary of coupler rewound with 65 turns.
L²—Variometer.
C'—Variable air condenser (vernier) .0005 mfd.
C —Fixed mica condensers .002 mfd.
R —Filament rheostat 30 ohms.
R'—Potentiometer.
A —Filament battery (three dry cells).
B —Plate battery (45 volts).
D —Crystal detector.
T —Audio frequency transformer.
P —Telephone receivers.
VT—Vacuum tube (UV-199) and socket.

There are of course other tubes which may be used in this circuit, depending upon the experimenter's choice. In case any other tube is used, the values given for the filament battery and filament rheostat will have to be changed to suit the tube used. Higher plate voltage may be used and is recommended although a "C" Battery in the grid circuit will be necessary in this case.

The primary of the variocoupler should be so tapped that the number of turns can be varied one at a time. This can be accomplished if two multipoint inductance switches are used, one for coarse and the other for fine tuning. The popular variocoupler on the market at the present usually has about twenty or thirty turns of wire on the rotor. The rotor therefore, will have to be rewound using smaller wire or by bank winding until there are 65 turns of wire on it. The set will tune more sharply if the rotor is bank wound, using a larger size wire because the added resistance of the small size wire will detract from the selectivity of the set. The secondary is tuned with a vernier condenser having about 23 plates. The vernier will enable the user to do much finer tuning which may mean the difference between hearing and not hearing a distant station or between hearing one or two stations at once. Another tuning control is the variometer which is placed in the plate circuit of the tube. By using a variometer for the radio-frequency coupling, there are several advantages gained. The experimenter will usually find that the signal strength is greater using this method of coupling, rather than transformer coupling. One reason for this is that it is very difficult to design a transformer coupled set which will give satisfactory voltage amplification through the transformer. Another advantage lies in the fact that the variometer can be used for tuning out undesirable signals.

The potentiometer R' which is connected in the grid circuit may or may not be necessary. If the experimenter is very close to a high-powered station, this potentiometer will stabilize the set and prevent the tube from oscillating. Any very loud signals tend to make the set unstable so the resistance of the potentiometer will have to be adjusted for each different intensity of signal strength. If great care is taken to keep all grid circuit wires away from the plate circuit wires and by using the tube recommended, no trouble due to instability should be encountered.



A highly selective reflex circuit using one tube and a crystal detector.

In tuning this set, remember that any set will be more selective and less affected by atmospherics when the coupling between the primary and secondary is very loose. For this reason a variocoupler has been used and by its use signals otherwise unintelligible will be pulled through persistent interference.

In selecting a crystal detector, there are several points which should be kept in mind regarding the mounting. The crystal should be firmly mounted in a cup so arranged that this cup can be removed at any time without great difficulty. The cup should be held firmly in the mounting so that there will be no possibility of the cat whisker losing its adjustment. The cat whisker which can consist of one small wire or a bundle of small wires, should be mechanically rugged and have some arrangement by which its pressure on the crystal can be adjusted. The best results seem to be obtained when the contact is very light although the adjustment is very easily disturbed in this case.

WOAW, the Fine New Broadcasting Station of the Woodmen of the World

STATION WOAW, of the Woodmen of the World Life Insurance Association Headquarters at Omaha, Nebraska, has been on the air since April 2nd, when it was officially opened. Since then it has attracted the notice of "listeners in" in every part of the United States as well as distant outside points. WOAW was designed and constructed by the Western Electric Company engineers who established communication between Arlington, Virginia, and Paris, France.

(C. Western Electric)

Fig. 1. The antenna system of station WOAW, the new broadcasting station of the Woodmen of the World, at Omaha, Nebraska.

The Woodmen of the World Life Insurance Association, while fundamentally interested in insurance, has demonstrated its policy as being more than an insurance proposition. In fact, the policy of the Woodmen of the World Life Insurance Association is to keep pace with progress in all lines of human endeavor. The War Memorial Hospital to be officially dedicated at San Antonio, Texas, July 4th, has been constructed by the Woodmen of the World to care for members who have been disabled by disease. It marks a new step in the history of fraternal insurance. Plans are also being laid by the executives of the Woodmen of the World for a home for the aged members of the Society and for orphans of Woodcraft. Another feature introduced by this Society is the extension of loans to members to enable them to build their own homes. The construction of Radio Station WOAW was the culmination of this policy.

Over $50,000.00 has already been expended in equipment and management of this station and the officers are sparing no funds to make it one of the best privately owned commercial radio stations broadcasting in the United States.

Not only have the distance attempts met with satisfying results, but success has been achieved in procuring diversity and high quality in the broadcasting programs, as is testified by the expressed approval of "listeners in" from every state in the Union, as well as Canada, Mexico and Cuba. Station WOAW, in spite of the brief period of operation, has already reached such distant points as Los Angeles, Vancouver, Miami, Bangor, Newfoundland, Quebec, Porto Rico, Havana, Guadalajara, Mexico and Nova Scotia.

The farthest distance reception of WOAW acknowledged was a message from the radio operator on the S.S. "White," at that time located 1,200 miles south of San Pedro, California, making an approximate bee line of 3,000 miles from Omaha.

That WOAW attracted the attention of radio fans extensively is indicated not only from the point of its

(C. Western Electric)

Fig. 2. W. A. Fraser, Sovereign Commander of the Woodmen of the World, making the dedication speech at the opening of the new WOAW broadcasting station.

distance acknowledgments, but also in view of the vast number of letters, telegrams and telephone calls which have flooded the headquarters. During the first week of broadcast more than 50,000 of these communications had been received at the offices and a force of 10 telephone girls, 15 typists, 10 stenographers and numerous

An Army in the Field Depends Upon Radio

By Carl H. Butman

EFFICIENT communication in the army is coming more and more to depend upon radio, and in order to keep abreast of its rapid development the Signal Corps of the United States Army maintains a complete and modern radio research laboratory at Camp Alfred Vail, N. J. Here the development of new and special apparatus for the several arms of the service is planned and perfected. A number of America's foremost radio engineers are engaged in the laboratory upon radio problems. A radio school for military students is also conducted at Camp Vail, where men from the different corps are trained as experts.

Functions of the Signal Corps do not comprise radio communication solely, but include all means of signaling running from visual, through the pigeon service, line telegraphy, cables, telephone work, including field service to the latest methods of radio communication. The Signal Corps also includes meteorological and electric time services.

In time of war, a signal officer pointed out recently, victory or defeat has sometimes hung upon the transmission of a single message, and the importance of communication is so great that no engagement can be successful without a well-planned system of communication. In the army efficient communication systems are maintained in time of peace as well as war. This makes it necessary for the Signal Corps to keep up to date and, when possible, to be a little ahead of the times. Many commercial devices and systems now used were originated in the Signal Corps for military use long ago.

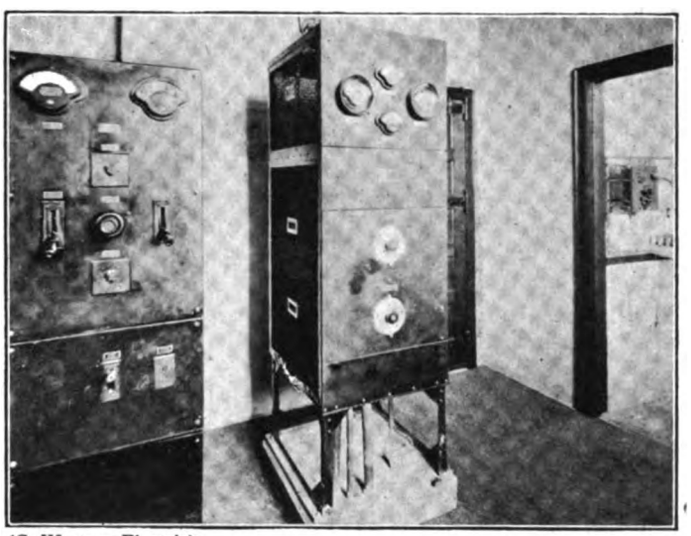
Today a network of radio stations extends to all quarters of the country, with a message center in Washington. High powered stations carry dispatches from coast to coast in record time, and no military command is out of touch with Washington for an appreciable length of time.

The installation of a system of modern 1½ kilowatt vacuum-tube stations connecting all centers of military activity has been practically completed. For the transcontinental circuit stations have been established at New York, Washington, Indianapolis, Omaha, Salt Lake City and San Francisco, with one nearing completion at Cheyenne. Similar stations have also been installed at Atlanta and St. Louis. In addition, all the important aviation fields will soon be connected with the radio system. Most of the big stations are equipped with remote control apparatus permitting operation of a transmitter at some distance and the reception of incoming messages by loops and six stage radio-frequency amplifiers in the main offices. Communication is maintained through these sets by means of the continuous wave telegraphy method, but the stations are also equipped for radio telephony and buzzer, modulated radio telegraphy.

The importance of radio to an army in the field was shown during the operations of the First American Army in the Meuse-Argonne battle, when six hundred radio receiving sets were used for receiving airplane reports alone. The operation and maintenance of these receiving sets required the services of about 5,000 radio specialists, most of them recruited from the ranks of American amateurs at the outset of the war.

Radio for communication between infantry regiments and battalions is the most important link in action. Front line wired telephone and telegraph communication is constantly interrupted by shell fire and bombs. Farther to the rear, wire communication is more dependable and there radio becomes more of an auxiliary service.

With the exception of brigade to regiment communication, which is spark radio, all ground radio within an American field army is of the vacuum tube or continuous wave type.



(C. Western Electric)

Fig. 3. Partial view of the transmitting room of the new station of the Woodmen of the World at Omaha. A standard Western Electric transmitter is used.

In army corps headquarters, as well as large artillery and air units, powerful vacuum tube sets installed on tractors are employed. Divisions and regimental units in the field are equipped with compact chest-type tube sets. In advanced posts, "V"-shaped antenna supported by 20 foot bamboo poles are used.

(*Continued from preceding page*)

other general employees was necessary to cope with this enormous volume of communication. Over 300,000 pieces of mail matter have left Station WOAW in answer to communications from radio fans.

The studio is divided into four rooms—reception room, artists' room, operating room and power plant. The reception room and artists' room are furnished with beautiful velvet lounges and mahogany chairs for the convenience of both performers and visitors or guests of honor. Gorgeous draperies of plush are used not only for purposes of decoration, but also to muffle all sounds. Sound-proof glass doors and heavy rugs make the studio practically sound-proof at all times.

At the present writing one of Nebraska's well-known artists, Mr. Henri Domshyte, is painting a series of canvases for the studio. Mr. Domshyte is a modern impressionist and his work has been attracting much attention of late. In view of the fact that his pictures are being made to fit the color scheme of the studio as well as to express his philosophy of painting, it is expected that thousands of people will visit this studio not merely to learn about the radio station, but also to satisfy their interest in art. In fact, WOAW is claimed to be the only station in the country that can boast of this unique decorative arrangement.

A Simple Variable Grid Leak

By "Sigma"

TUBES of various makes require different values of grid leaks. These values vary from 1½ to 5 megohms, and the correct size can be found only by experiment. Although different leaks manufactured in cartridge form are very good, there is the expense to look at, as several would have to be bought of different values while only one would be used. For this reason the leak described below should be very popular and, in addition, the appearance is not an eye sore.

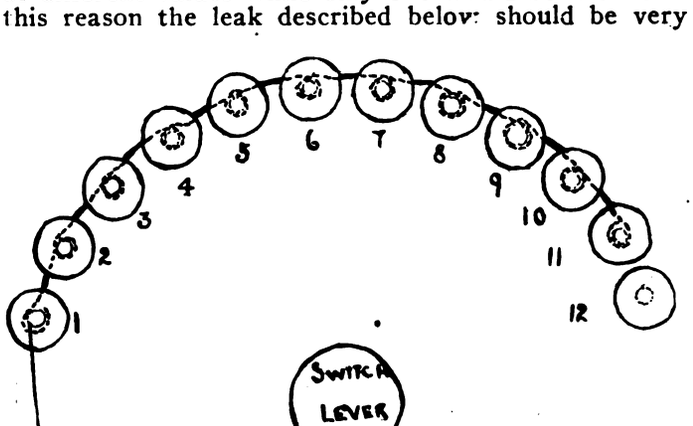

Fig. 1. Method of making a variable grid leak by fastening an India ink soaked string under the nuts of tape.

The parts to make up this piece of apparatus are easily obtainable and should not cost more than an ordinary grid leak. The following will be required: A switch lever, 12 contact studs with two washers each, about a foot of thin twine, some India ink and the hard rubber or other insulating material for for mounting.

Drilling the holes to mount the switch lever and contact studs is carried out in the usual manner. The twine is soaked in India ink and allowed to dry. When perfectly dry it is taken between the washers on the contact studs from 1 to 11, the last stud being left disconnected. The leak should now be connected to the condenser as shown; thus, when the switch is at 1 the condenser is short-circuited, while from 2 to 11 different values of leaks are obtained. When on stud 12 the leak is entirely disconnected; thus all the combinations normally required are easily obtained with a simple and cheap piece of apparatus, which the average experimenter can make up in about an hour.

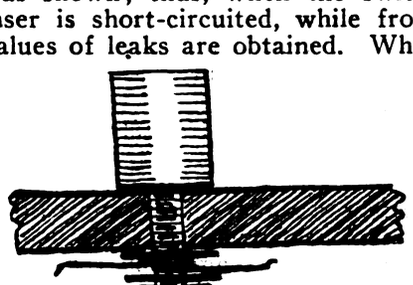

Fig. 2. Method of fastening the string to get good contact. It is wrapped around the shank under the washer.

Importance of Minor Things in Radio

By R. L. Dougherty

FEW people, either when they are constructing or operating a radio set fully realize the importance of some of the "minor things" they overlook or carelessly neglect. Some of these things may appear trifling but when they are multiplied together it is a wonder that some sets even as much as peep. A few of the "minor things" are:

Using too much flux when soldering connections. This causes a high resistance leak because of the habit of the flux to spread and collect dust and dirt, thus lowering the efficiency of the set.

Not soldering connections. Brass and copper have the habit of corroding. When you make a connection and simply fasten it under a screw, you are courting high resistance because the metallic parts will corrode. *Solder all your connections.*

Not insulating your lead-in properly. People have a bad habit of just letting their lead-in come through the top of an open window, touching the walls. In general they bring it in "any old way at all." Were you to visit a commercial station, or take a look at the radio shack aboard a naval vessel, you would note the fact that the lead-in was very well insulated by insulators hanging from the ceiling, or some other method, and that also the inside lead-in was of very heavy copper wire, No. 2 or No. 0 being used.

Letting dust collect. Many sets do not receive a good cleaning from the time they are installed until they are broken up or relegated to the "junk pile." Dust collects between the switchpoints, binding posts and every place possible, forming innumerable paths of escape for the minute currents and seriously cutting down the efficiency of the set.

Insulating. Where leads cross on the interior of a set in close proximity, it is better to use a few inches of insulating material in the form of spaghetti or rubber tubing than to take chances of a short when the set is moved or an adjustment changes some interior part of the set. An ounce of precaution, or an inch of insulation, is worth $6.50 or a couple of new tubes or a new pair of phones.

Phones. These devices were constructed as a means of hearing signals, not as a means of showing your friends how much you know about the workmanship of different parts. Do not take off the ear pieces, tap the diaphragms, or fool with the wiring, unless you understand just what you are doing. The phones took a couple of hours of an expert's time to adjust and your taking the caps off destroys his work. Phones are sensitive instruments and wired with copper wire that is finer than the hair on a man's head. They will not stand abuse. Do not test them out by putting them across a battery. They will click if you simply touch the two ends to your tongue, and rub the terminals together. If they don't work, after you have been using them, take them back to the manufacturer and let him fix them. He will be able to do it—but not if you try to do it first.

A CW Hook-up That Really Works

By R. W. Emerson Decker, 2UA

THERE have been so many different hook-ups and various suggestions about CW sets that the novice starting in the transmitting game is really bewildered.

For CW work an aerial of about sixty to seventy feet should be used. Four wires spread three feet apart is necessary. Good porcelain insulators should be used and the guy wires should be broken up with insulators every ten feet or so. This tends to stop the reradiation which is common with CW transmitters.

The lead-in should be a cage about six inches in diameter and carefully insulated throughout. Be very careful when bringing it through to the set.

A counterpoise should be used and this should be also carefully insulated. This should fan out under the aerial for a diameter of about forty feet and should extend past the aerial a few feet. The height of the counterpoise from the ground should be about ten to fifteen feet. If the space about the station does not permit the erection of the counterpoise under the aerial have it at right angles; it works equally as well and the wave seems to be sharper.

Now that we have the aerial and counterpoise ready we should start on the transmitter itself.

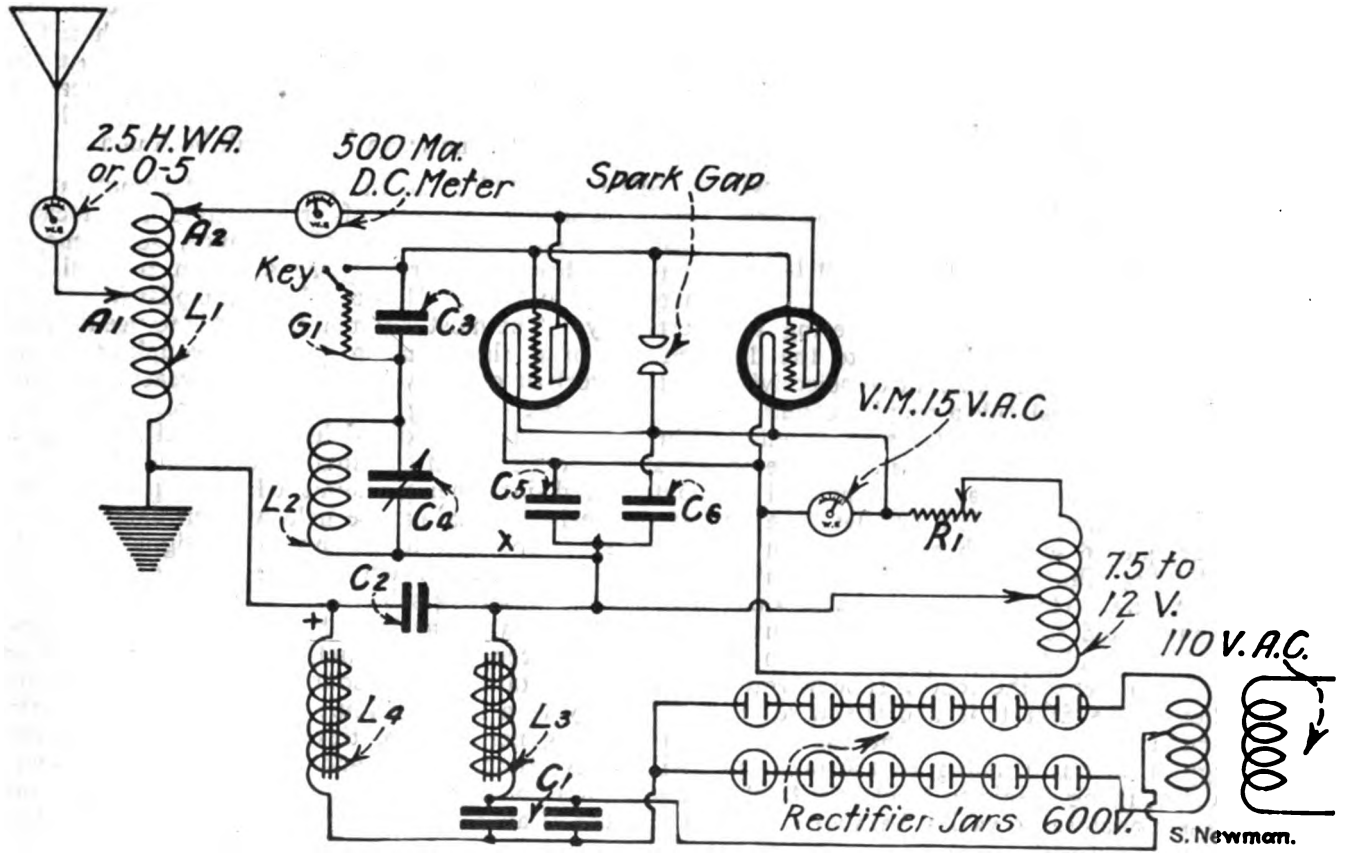
The circuit used here is very easy to operate and adjust and will work with practically no adjustment, but with some hard study and careful tuning will step out in great style. This hook-up can be used with five-watt tubes or the next size, 203 or fifty watters.

On looking the circuit over it is easily seen that L^1 is the main inductance. This is a tube 7 inches long with 30 turns of No. 10 BSC wire. A point here to remember is to insulate this thoroughly. It should be six inches in diameter.

There has been quite some argument on the merits of ribbon or heavy wire for inductance, but wire is generally used.

L^2 is the grid coil and is made with fifteen turns of wire on a tube slightly smaller in diameter than L^1. This coil is placed in the bottom of the main inductance and the wire should be wound in the opposite direction to that of the other coil.

L^3 and L^4 are iron chokes, 1½ henry, and 500 M. A. C^1 and C^2 are 1 mfd. condensers. The Western Electric 21-A.A. condensers can be used here and work very well.



A neat and powerful CW or phone transmitter circuit. If you have been looking for an efficient transmitter construct this and you won't go wrong.

C^3 is a mica or air condenser of .0005 or .005 mfd. capacity; C^4 is a variable condenser of about .0005 to .001 mfd.

C^5 and C^6 are .001 fixed paper condensers.

G^1 is the grid leak of 10,000 to 15,000 ohms resistance. R^1 is a heavy rheostat. This should be able to carry 5 amperes continuously without heating. While some claim a rheostat is not necessary here, it is much safer to use it as the voltage may change at times and a rheostat is cheaper than burning out tubes.

A^1 is the wave length tap; A^2 controls the coupling; the hot wire meter should read to 0-2½ or more. The meter near A^2 is a 500 M.A. D.C. meter.

An AC 10 to 15 volt meter should be used in the filament lead, as in the diagram.

At the point marked X the lead may be broken and the secondary of the modulation transformer inserted.

Elementary Instruction for the New Army of Radio Beginners

Constantly Used Terms Explained in Plain Language for the New Radio Enthusiast

By Lynn Brooks

ABSORPTION: The loss of electrical energy radiated into space, due to the electric conductivity of surrounding objects. This effect is noticeable more in congested districts containing a number of steel or metallic structures, or objects that will conduct and absorb the energy radiated into space. It is very noticeable in places where there is a great deal of foliage, such as in or near forests. Absorption is frequently the reason for some signals being received from certain distances more easily than from others, and if you receive signals easier from the south than from the north a survey of the surrounding country will nine times out of ten prove that some intervening body, such as a forest, or a number of tall buildings is absorbing most of the energy from the northern point before it gets to you.

VARIOCOUPLER: A method of transfering the received energy from the antenna circuit to the detector circuit must be had if any amount of selectivity is to be achieved. To accomplish this a coupler generally is used. A coupler consists of a tube (stator) on which is wound numerous turns of wire. The inductance on this tube is varied by means of tapping it at various places. Inside of this tube there is a smaller tube or ball (called a rotor) placed so that it may freely rotate inside of the first tube. On this there is also wound a number of turns of wire. The wire on this tube is not variable, but is calculated to cover a certain number of wave bands and is variable by capacity when shunted by a condenser. In use, when the central tube or rotor is exactly parallel to the first tube and the wires in both tubes are running in the same plane the transference of energy from one winding to the other is maximum, and the coupling is said to be close. As the rotor is turned the transference varies, because of the inability of the lines of force generated by the first tube to cut as many wires as before, and the tuning is then said to be loosened. When the two coils are at right angles, the transference is at its minimum.

WAVE METER: A wave meter is a device by which it is possible to measure the frequency of an emanated electrical wave. It generally consists of an inductance of fixed value, a variable capacitance, a means of detecting or rectifying the impulse and a pair of phones, or small glow lamp so as to enable the user to determine when the circuit to be measured and the measuring circuit are in perfect resonance. On the condenser is placed a scale reading from 1 to 180°. This is generally plotted in the form of a curve on a graph in terms of an empirical scale. The coil of the wave meter, the constants of which have first been checked and the wave length plotted against a standard instrument, is placed near to the instrument to be measured, and the condenser is varied. If a received signal is to be measured, the detector and phones are used, and if a transmitter is to be checked, the small lamp is used in place of the phones and detector. As the condenser is rotated, the signal will be heard in the phones, or the small lamp will light up. At the point where the transference of energy is the greatest, the two circuits are in perfect resonance, and by looking at the scale, the wave length will be found.

SELECTIVITY: In the reception of signals, especially where a number of transmitters are located within a comparatively small distance, some means must be had of separating the different transmitters from one another. This can be accomplished in several ways. The most common method is to use a tuned circuit, or a circuit using inductive coupling rather than direct or capacity coupling. The reason for this is that as the coupling can be varied directly between the antenna circuit and the detector circuit, the signal that is undesired can be reduced to a minimum, without desired signal being diminished to any great extent. If the desired signal can be held without decreasing it in direct proportion to the undesired signal it is apparent that it will drown out the other or undesired signal. In obtaining selectivity in a circuit it is sometimes necessary to sacrifice the volume of a signal, but this is balanced by clear and untroubled reception of the wanted station. It is sometimes possible to obtain selectivity in a single circuit receiver because of the circuit's regenerative abilities. A regenerative circuit will always tune sharper and is therefore more selective than a non-regenerative one, but at the same time it has the disadvantage of re-radiating.

(*Continued from preceding page*)

The transformer secondary should be shunted with an .001 condenser. The transformer secondary should be short circuited when CW is used. It will also be necessary to change the value of the condenser C^4 every time the set is changed from voice to CW.

The rectifier used is the electrolytic type. The plates should be about three inches long and from ⅛ to ½ inch in width. They will pass 200 M.A. easily if about 1-32 of an inch in thickness. A point here necessary to advise is to use only pure aluminum and lead. Distilled water must be used.

The solution is made up of borax and water and it is also well to get good borax. If there is sparking in the rectifier it shows that poor aluminum has been used. Overheating and a great loss of efficiency will then take place.

L^4 and L^3, together with the condenser C^1 and C^2, will make a good filter system and will take the ripple out.

If U.V. 203, the 50-watt tubes are used, the grid leak may be left out at 750 volts, while with 1,000 volts plate current the grid leak should have a resistance of 250 ohms. If one tube is used about 500 ohms will be sufficient.

The condensers in the filter system will have to stand at least 2,500 volts.

This CW set is the best for short waves and it is fine for the 150 to 200 meter work.

Rectifying tubes can be used in place of the rectifier, but are more expensive to use than the jars.

If the set is put into a panel it will present a very fine appearance, but first the set should be experimented with and carefully wired so that no high resistance joints be made.

At a local station this hook-up was used with two five-watt tubes and a DX of 2,000 miles was obtained.

Be sure that you have wired the set correctly before testing out the tubes, as a mistake can easily be made, and a burned out tube may be the result.

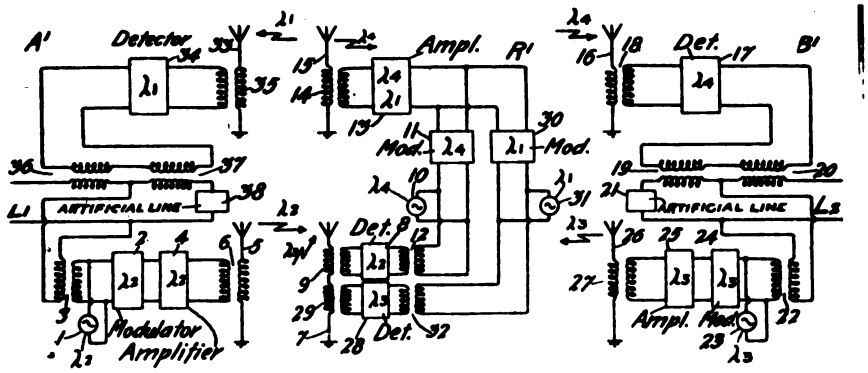
High Frequency Signaling

No. 1,452,857: Patented April 24, 1923. Patentee: E. H. Colpitts, East Orange, N. J.

THIS invention relates to high frequency signaling, and more particularly to the relaying or repeating of telephonic messages transmitted by means of high frequency carrier oscillations, modulated in accordance with the form of the message wave.

this by receiving at a repeating station a modulated wave transmitted from either or both of two terminal stations. On receiving a modulated wave at the repeating station a new carrier frequency is substituted having a value different from the carrier frequency for which the repeating station's receiving apparatus is tuned. In other words,



Colpitts' new method of modulating telephone signals.

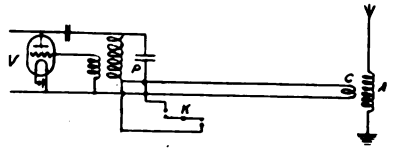
It is an object of the invention to provide a system for two-way repeating and to prevent, at a repeating station, a useless local circulation of power, which gives rise to the objectionable phenomenon known as "singing."

The invention provides for accomplishing the receiving apparatus at the repeating station will not be receptive to the carrier wave transmitted from that repeating station, and the objectionable local circulation of power is prevented. However, the new carrier wave is received at the proper terminal station.

Wireless Transmitter

No. 1,452,900: Patented April 24, 1923. Patentee: W. T. Ditcham, Twickenham, England.

THIS invention relates to wireless transmitters of the inductively coupled type. In accordance with this invention the in-



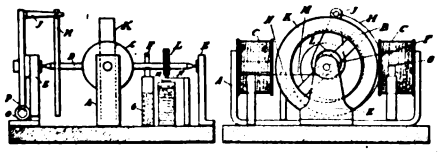
W. T. Ditcham's method of using inductive coupling in sustained wave transmission.

ventor utilizes a primary and a secondary circuit, in which a portion of the inductance of one of the circuits is extended to affect the other circuit, and means is provided for short-circuiting the extended portion for the production of signals.

Wireless Telegraph Calling

No. 1,452,925: Patented April 24, 1923: Patentees: W. H. Nottage and T. D. Parkin, Chelmsford, England.

THIS invention relates to wireless telegraphic calling devices of the type in which impulses are transmitted at regular



W. H. Nottage's system of calling or ringing bells by radio at predetermined times.

intervals and are received by a balance wheel relay, or the like, which has a natural oscillation period equal to the interval between successive impulses so that, though the relay may be unaffected by ordinary signals, yet when a train of impulses at predetermined intervals is incident upon the receiver the oscillations of the relay are increased by the impulses sufficiently to enable it to actuate a bell or other signal or operate in some way an electric circuit for the control of apparatus.

According to this invention we employ for transmitting and receiving the impulses timing mechanism, comprising a spring controlled balance wheel oscillated by an electromagnet, the circuit of which is interrupted by the oscillations of the wheel.

Telephone Receiver

No. 1,452,859: Patented April 24, 1923. Patentee: Lambert Schmidt, Brooklyn, N. Y.

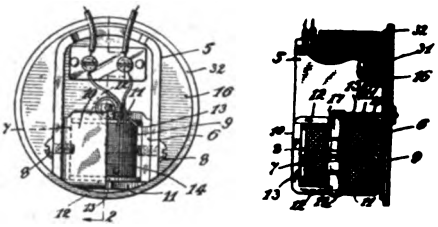
THIS invention relates to a loud-speaking receiver for use in connection with apparatus employed for the purpose of establishing wireless telephonic communication.

Generically considered, it is the primary object and purpose of the invention to provide a receiver of the magnet type which will be highly sensitive and instantly responsive to the slightest variations in polarity of the alternating currents coming in over the line.

More particularly the invention comprehends a radically new form and construction of the armature, having a resiliently balanced suspension in the bore of the translating coil spool. This armature is of cylindrical form, and the pole shoes of the permanent magnet are so related to the ends of the armature at opposite sides thereof that the magnetic flux, acting over a relatively small area, produces an instantaneous responsive movement of the armature to the slightest pulsations of the alternating currents passing through the translating coil.

As a detail item of improvement in instruments of this character, the inventor provides a two-part armature and fulcrum means therefor, which is secured and held in assembled relation with the armature parts when the latter are connected so that the armature and its fulcrum in fact constitute a single unit and capable of assemblage in operative position by the mere insertion of the armature through the bore of the coil spool.

In general the present improvements provide a telephone receiver as above characterized, which, though highly sensitive in its



New method of locating the magnets of a telephone with regard to the diaphragm.

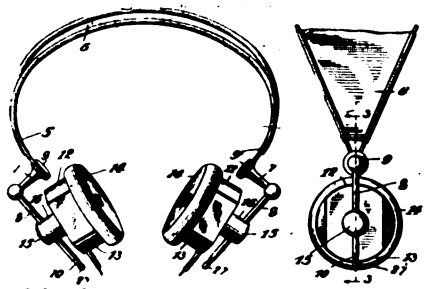
action, is nevertheless composed of simply and substantially constructed elements which are capable of operative association in very compact relation and may be confined within a casing of appreciably smaller size than it is possible to use in instruments of this character as heretofore constructed.

Head Receiver for Telephones

No. 1,452,851: Patented April 24, 1923. Patentee: Lambert Schmidt, Brooklyn, N. Y.

THIS invention relates to head receivers for telephones, and is more particularly designed for use in connection with radiotelephone apparatus, though not necessarily limited in this respect. It is the primary object and purpose of the present invention to provide a head receiver for telephones of that type wherein the two receivers are connected by a more or less elastic or flexible head band or bridge.

More particularly it is the aim and purpose to provide an improved adjustable connecting means between the receivers and the



Schmidt's flexible headband for telephone receivers.

ends of the head band whereby the receivers may be readily positioned in accordance with the size or physical peculiarities of the wearer's head so that they will fit snugly against the ears and thereby exclude extraneous sounds or noises.

Radio Supervision in Samoa

ALTHOUGH the radio regulations for New Zealand have been extended to apply to Samoa, it is reported that more latitude is given the amateurs, and that an effort to regulate broadcasting stations is being made before interference begins. Samoa is designated as the Fifth New Zealand Radio District, with the officer in charge of the Apia radio station as inspector of local reception and transmission.

Except that it is necessary to secure a license and pay a small license fee, amateurs are unrestricted in radio reception; but licenses are not to be issued for circuits which cause interference. Amateur transmitting stations in Grade I require the supervision of a licensed operator.

Radio and the Woman

By Crystal D. Tector

Last Saturday, F. H. was laid up with his usual spring assortment of sneezes and coughs that he pleasantly calls his "daily dozen," and therefore could not attend the Milk Fund Boxing Exhibition. He was grouchy all day long until about two o'clock. You know how a husband gets when he has "a bad cod in by ead." Well, after numerous friends had dropped in during the morning to sympathize with him and try to tell him that there wouldn't be a "scrap" anyway on account of the rain, and then rushed off in their cars for the fight, he felt real nice. We had the laugh on them after all, because we sat home and heard the entire fight right down to the last blow and Humphries making the announcement, and were cozy and warm when the other folks were hurrying home in the rain, and had to buck the crowds n'everything. Then he cheered up and commented again on the wonders of radio.

* * *

Another thing that put friend husband's nose out of joint was the fact that we received an invitation to go to the dedication ceremonies of the new "Broadcast Central" of the Radio Corporation, at Aeolian Hall. Of course he couldn't go, so I told his brother Jack that he would have to escort me. Well, I never have been in a real big studio before, and I haven't gotten over it yet.

We got off at the sixth floor and found a small quiet crowd of people standing conversing quietly and all seeming to know one another. We hadn't been standing there more than a minute when a man appeared mysteriously at our elbow and asked us if we wouldn't like to look around the studios. Before escorting us through he explained that there were two studios, one called the Jazz studio and the other the Classical studio, but for briefness sake he called them studio A and B.

They didn't go very wrong when they called A the "Jazz" studio. The color effect of the hangings and walls is enough to make anyone want to "raise the dickens with a sax." The walls were finished in light blue and green and all the woodwork in salmon pink, with the hangings and draperies the most vivid colored cretonne that you could imagine. Even the furniture is brightly colored, and how anyone could even sit still in this room is more than I can imagine.

The studio "B" or classical studio is just the antithesis of the Jazz room. It is quietly done in old ivory and brown with dark hangings of maroon and old gold. It was the most quieting and soothing thing in the world, and one was instinctively hushed by the very quietness of it. It is simply marvelous what an interior decorator can do with your feelings with a few artistically placed lights and some wonderful quiet colors. Here the chairs were all deep, roomy, comfy and cushiony, and just the type to rest one.

What impressed me the most was the very "deadness" of both of these places. You actually could think out loud without disturbing yourself. Our guide explained that this was accomplished by special walls, which are of wax treated muslin held away from the real wall, with a dead air space between. It was wonderful.

Then we were taken into the control room and, wonder of wonders, we met OON and OHN, the two announcers that are so familiar to all of us. I just talked to them as though I had known them all my life. Isn't it funny how well acquainted you can become by radio with a person?

After a while, when we had gone upstairs and absorbed a lot of technical explanations that I can't remember, we went down and heard all the dedication speeches.

Then the Radio Corporation very kindly provided the nicest little supper and we were left to wander around and poke and question till we became tired and went home, feeling like we had stepped from a fairy land of delights and never ceasing wonders.

And all this time, Friend Husband was sitting home hearing the speeches, and wondering what kind of a time we were having. Oh dear, some men do have hard luck, don't they?

Anothera Slam at Mike Podhorn—WOW—44 States!

From Bart Geib, Shreve, Ohio

WAS just looking over RADIO WORLD and noticed some of the slams at Mike Podhorn. Although I did not get the issue containing his letter I think, after he sees my record, he will "seek the cause within himself."

I would like to know what type and kind of apparatus he is using. Well, here goes for my record:

Alabama—WMAV, WHAN, WSY, 5XR; Arizona—KDZA; Arkansas—WOK; California—KHJ, 6XA, 6ZK, KWH, KFI, KWG; Canada—CFCA, CFCF, CFAC, CJCG, CJCD; Colorado—KFAF, 9XAQ, 9ZAF, KLZ; Connecticut—1ZKA; District of Columbia—NOF, WCAS, WMW; Florida—WDAE, WDAL, WIAZ; Georgia—WSB, WGM, WDAJ; Illinois—WMAQ, KYW, WDAP, 9XU, WOAG, WAAF, 9ZK, 9ZM; Indiana—WOZ, WLK, WOH; Iowa—WGF, WOC, WLAS, WEAB, WOI, WEAZ; Kansas—WEAD, WBL, WAAP; Kentucky—WHAS, WIAR; Maine—WLAN; Maryland—WEAR; Massachusetts—WGI, WMAF, 1XA, 1XJ, WBZ, WNAC, 1XAE; Michigan—WCX, WWJ, WWI, KOP, WHW, 8XF, 8XAE; Minnesota—WLAG, WJAP, WAAL, WMAF, WCAS; Missouri—WHB, WDAF, KSD, WOS, WCK, WAAN, WOAL; Nebraska—WAAW, WIAK, WFAV, WCAJ; New Jersey—WOR, WJZ, WAAM, WBAF; New Mexico—KOB, 5YQ; New York—WGY, WGR, 2XI, WRW, WHAZ, WEAF, WHAM, WMAC, 2XB, 2XY, WBAY, 2ZK, 2XL, WHN; North Carolina—WBL; Ohio—WJAX, WHK, 8YD, WBAV, WOC, WWB, AN4, WLW, WMH, WAAY, WFO, AQ6, WPAL, WBAJ, 8YAE, WPL, WEAH, WRK, WJAK, 8XR, WOAC, WMC, WMAN, WJD, 8ZO, WQAF; Oklahoma—WKY, WLAL, 5XZ, WPAC; Oregon—7XI; Pennsylvania—KDKA, WCAE, WIP, WBAK, KQV, WQAA, WGL, 3CDP, WFI, 8ZAE, WNAL; Porto Rico—WKAQ, WGAD, 4OI; South Dakota—WCAF; Tennessee—WKN, WPO, WNAV, WAC; Texas—WPA, WBAP, WFAA, WJAD, 5XAD, WOAI, WCM, WSAV; Utah—KZN, KDYL; Vermont—WCAX; Virginia—NAA; Washington—KNF, KQT, KFZ; West Virginia—WAAO; Wisconsin—WIAO, WCAY, 9XM, WHA, WAAK; Cuba—PWX; Louisiana—5YR; Wyoming—KFBF. Steamships—KKW, WCL, WGN.

That's a record to be proud of, I think. I am using Clapp-Eastham H. R., with H. Z. amplifier and Magnavox. I am an ardent radio-golf fan since it started I've started a list like the following three or four entries: WHAS—Alamo Theatre Orchestra; WDAP—Jack Chapman's Orchestra; WJZ—Vincent Lopez's Orchestra.

Let's see who can get the biggest list like that. Don't list the same orchestra twice, but you can list the station twice, with a different orchestra, church, pipe organ, chimes, instrumental trio, quartette, etc.

I've got 58, and will send in my list as soon as I get 75.

Well, I think my record will make even Mr. Lindstrom sit up and take notice. I've got the date and acknowledgment of signals heard from most of these stations.

* * *

The U. S. at Your Finger Ends

From Paul Richardson, 406 Baltimore Bldg., Oklahoma City, Okla.

I BUY the RADIO WORLD each week and enjoy it very much, for the reading is fine. I have a single set circuit that I have made and have heard from coast to coast and from Winnipeg, Canada. South to Houston, Texas. Here are a few stations that I have heard: KSD, WGM, WSB, KYW, WDAP, WAAD, WLW, WFAA, WOC, KLZ, KOP, WWJ, WCX, WBAP, WEV, WLW, WDAF, WHB, WGAT, WHAS, KHJ, WGI, WHAD, WAAB, WBAY, WGY, WOAI, KZN, WMAF, WEB, CHCF, WOAE, WSY, WHA, WLAG, WMY, RFAF. My antenna is 40 feet high, 75 feet long, ground runs five feet to water pipe.

THE editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

* * *

From Smith to Smith—Oh, Smith!

From A. L. Smith, 676 Euclid Ave., Beaumont, Texas

IT seems that everybody is taking a crack at Kenneth Smith, of Birmingham, Ala., so I will take one just to be in style.

My set is a single-tube set (WD-11 tube), using a 43-plate condenser, variocoupler and grid leak. Some of the stations I have heard are as follows: KHJ, KWH, KFI, Los Angeles, Cal.; KPO, KUO, San Francisco, Cal.; WLAG, WLB, Minneapolis, Minn.; WCX, WWJ, Detroit, Mich.; WWI, Dearborn, Mich.; WGY, Schenectady, N. Y.; WOC, Davenport, Ia.; KDKA, Pittsburgh, Pa.; WJAZ, WDAP, KYW, Chicago, Ill.; KGO, Altadena, Cal.; PWX, Havana, Cuba; WSB, WGM, Atlanta, Ga.; WOI, Ames, Ia.; WHA, Madison, Wis.; KDZU, KFAF, WFEL, KLZ, Denver, Colo.; WJZ, Newark, N. J.; WGF, Des Moines, Ia.; WHB, WDAF, WOQ, WMAJ, Kansas City, Mo.; WLW, Cincinnati, O.; WOS, Jefferson City, Mo.

I have received as many as 28 stations in one night. To date I have received 79 stations. Who can beat this with one peanut tube? Let's hear from you DX Nite Owls!

* * *

A Nice Month's Work

From Osborne Huckley, 2436 W. 33rd Street, Denver, Colo.

I AM sending you my record for one month's reception:

KDKA, Pittsburgh; KDYL, Salt Lake City; KDYS, Great Falls; KDZQ, Denver; KFAB, Portland; KFAD, Phoenix; KFAE, Pullman, Wash.; KFAF, Denver; KFBK, Sacramento; KFCI, Los Angeles; KFDF, Casper; KFEL Denver; KFEP, Denver; KFFQ, Colorado Springs; KFZ, Spokane; KFI, Los Angeles; KGW, Portland; KHD, Colorado Springs; KHJ, Los Angeles; KUS, Los Angeles; KLN, Del Monte, Cal.; KLZ, Denver; KPO, San Francisco; KYW, Chicago; KZM, Oakland; KZN, Salt Lake City; WAAH, St. Paul; WAAL, Minneapolis; WAAP, Wichita, Kansas; WBAP, Worth; WRAD, Marion, Kansas; WRR, WCAS, Minneapolis; WDAF, Kansas City; WDAO, Dallas; WDAP, Chicago; WEAH, Wichita, WEAY, Houston; WFAA, Dallas; WGM, Atlanta; WHAS, Louisville; WHA, Madison, Wis.; WHB, Kansas City; WIP, Philadelphia; WUAP, Duluth; WLAG, Minneapolis; WLAU, Waco, Tex.; WLAZ, Warren, Okla.; WLK, Indianapolis; WLW, Cincinnati; WMAU, Kansas City; WMAQ, Chicago; WMC, Memphis; WOAI, San Antonio; WOC, Davenport; WOO, Philadelphia; WOS, Jefferson City; WPA, Fort Worth; WRAD, Marion, Kansas; WRR, Dallas; WSB, Atlanta; WWU, Detroit; CFCN, Calgary, Can.; CHBC, Calgary, Can.; CKCK, Regina, Sask., Can.; CFAC, Calgary, Can; AA-3, Denver.

I am using a radiotron WD-11 (peanut) tube and get best result with a "B" battery of 18 volts. My aerial is one wire 40 feet high and 100 feet long. Any further information concerning this set will be furnished on receipt of stamp.

(C. Photonews)

Brooklyn to the fore! William Delaney in order to hold up the record for Brooklyn and show them that they can do it in that man's town as well as any other, made a DX record of receiving 40 stations in one evening. The receiver is entirely home made. As a starter, he charted a station 1000 miles away and then worked around, stretching his legs at every step. Canada, Cuba, Texas, Nebraska and all the intervening territory was covered on detector and two stages of audio-frequency. How's zat?

Digitized by Google

Answers to Readers of Radio World

Where can I obtain a complete hook-up of the circuit shown by C. White in RADIO WORLD *for March 3, on page 11? What voltage is necessary to obtain good results with this circuit?—Henry M. Schwab, 201 Buell Street, Muscatine, Iowa.*

The circuit was shown complete in the issue you mention. As previously stated we do not furnish blue prints. 1½ volts for the A battery and 22½ volts for the B will be sufficient.

* * *

In RADIO WORLD *for May 20, 1922, you published a diagram of a three circuit regenerative set. Will you kindly advise me where I can obtain a diagram for an additional two stages of amplificaiton? What is the grid condenser and leak capacity in the diagram?—James B. Thompson, Toronto Water Works, Toronto, Canada.*

If you will refer to page 26 of RADIO WORLD for March 31, you will find the diagram you desire. The grid leak in the diagram can be omitted, as it is not necessary with the circuit you mention. In the original diagram the condenser and grid leak should be .0025 mfd. and 1-2 megohms. If you intend using the 1½ volt tubes would advise using a variable grid leak, as these tubes are somewhat critical as to leak resistance, and better results can ofttimes be had by the use of a slightly different capacity of leak.

* * *

In RADIO WORLD *for March 24 there appeared an article by C. White on combining radio-frequency and regeneration, and mention is made of using a condenser of .25 mfd. capacity. Can these be purchased, or do they have to be made? If I have to make them kindly give me the directions.—H. E. Worldon, 1205 Pacific Ave., Peoria, Ill.*

If you will refer to page 8 of RADIO WORLD for April 14 you will find the information you desire as to the construction of large size telephone condensers. The article is by C. White and fully describes the method of determining the capacity of a condenser and how to build it up to any desired capacity.

* * *

Kindly refer me to a back issue containing a hook-up for the following apparatus: coupler, 43 plate vernier condenser, vernier, rheostat, grid leak, tube and all other necessary articles to make a one tube regenerative circuit.—A. A. Willaugham, 190 Major St., Toronto, Canada.

We refer you to any one of the following back issues in which you will find the hook-up you desire: RADIO WORLD, January 27, page 4; February 24, page 20; March 23, page 9 and page 13; March 10, page 20. Take your pick of any of these. They are all good circuits.

* * *

I HAVE constructed the Reinartz tuner hook-up as enclosed without using either the exterior coil or the amplifier, but cannot get anything except local stations, and even those are very weak. Can you suggest any way of alleviating my trouble? —O. C. Houser, McClure, Ohio.

The tube you mention is not exceptionally efficient in this circuit. Would suggest that you use the U. V.-200 as detector, or U. V.-201A. Use the regular Reinartz coils as inductance. Circuit diagram and full directions for the winding of these coils were given on page 23 of RADIO WORLD for January 13, 1923.

* * *

In RADIO WORLD *for April 21 you published an article by Mr. Turner on using the two-unit tube in connection with a receiver. When he states that he used the "other circuit," does he mean the one without the variable potentiometer in the circuit? Can I replace the coil with a variometer, and will a variable condenser increase the volume of signals in the receiver? Will 22½ volts in the plate circuit be sufficient? How should the circuit be tuned? Will the variometer mentioned work better than the tapped coil that is supposed to be used?—Ellwood F. Jahn, 5526 Catherine Street, West Philadelphia, Pa.*

When he states the "other circuit" he means the one without the potentiometer. Yes, you can replace the coil with the variometer. This will increase your selectivity to a great extent and give you much finer control of your tuning. The condenser will not increase the volume of your signals but will simply tend to make your set more selective and enable you to get much finer tuning. If you intend to use a variometer, would suggest that you place a tapped coil in series with it, to enable you to tune to the higher wave lengths when necessary. A coil 3½ inches in diameter and 6 inches long, wound with No. 22 SSC wire for five inches of its length and tapped at every 20 turns will suffice for this, unless you care to utilize honeycomb coils, which are much more efficient. The condenser you mention (11 plate) will be perfectly correct. 22½ volts B battery will be sufficient for one tube, but you will probably have more volume if you place 45 volts on the plate. In tuning this circuit you should throw your condenser to full capacity (100) and swing the variometer around until you hear signals. If you hear two stations on together, bring your condenser down and repeat the operation until your stations are separated and you are only hearing one at a time. If you are using the potentiometer, then bring the potentiometer into play until the signals have cleared up and the volume is the strongest with the least amount of distortion. The variometer will simplify your controls and make tuning easier.

* * *

In RADIO WORLD *for April 7, 1923, you published an article by Rumford in connection with "An All Wave Universal Receiver." Can I use a panel 9x12x¼ instead of the 7x14 specified? He states that the directions must be carried out specifically.—Michael Teaschner, 831 Van Duzen Street, Stapleton, Staten Island, N. Y.*

You may use any size, shape, or kind of a panel you wish. It makes no difference what size panel you use in the construction of a set, as long as the wiring is O. K.

* * *

Where may I find a circuit diagram for the following apparatus: Variocoupler, variable condenser, WD-11 tube, batteries, phones, and all other necessary apparatus to make a single circuit receiver. Are these tubes as good detectors as the ordinary six-volt storage battery tube? Where can the tubes be obtained?—R. D. Thornton, 1906 County Street, Portsmouth, Va.

We refer you to RADIO WORLD for April 21, page 21, column 2 (DX page) where you will find the circuit you desire. The WD-11 are classed as excellent detectors, and are extremely efficient and economical. When compared with tubes such as the U. V. 200 or 201 A, or the other six-volt tubes, the only difference is a slight decrease in the volume. They can be obtained in any up-to-date radio shop.

I have constructed a receiver, put up an outside antenna, and have been told by a neighbor that I must take down my wire because it crosses one corner of his garage. It is not attached to his property, and is 25 feet above his roof. He threatens to prosecute me, saying that I am disobeying the fire laws. The other end is anchored to a corner of a building, and I have full permission of the other to leave my antenna there. Can my neighbor make me remove my wire?—A constant RADIO WORLD *reader, Los Angeles, Cal.*

You are guilty of trespass and can be made to remove your wire. You are not disobeying the fire laws, but you are trespassing on another man's property. You will have to run your wire in such a manner that you do not cross his property, unless you get full permission from him, or anybody over whose property you pass.

* * *

I have recently tried out the new 201 A tube in connection with my receiver, and find that I cannot get as good results with it in connection with my detector as I do with my U. V. 200 tubes. I find that it is a much better amplifier than a detector.—D. R. Kilgore, Okemah, Oklahoma.

This tube is used as both detector and amplifier, but works much better as amplifier than as detector. It will work well as detector, but the ideal combination is to use it as amplifier with the regular U. V. 200 as detector. You will be able to obtain much better results in any circuit employing regeneration if you use variable grid leaks.

* * *

I have built the Sorenson circuit described by Ortherus Gordon in your issue of Jan. 20, and have had wonderful results with it, but fear that I will have to junk it after May 15. Can this be fixed so that I can retain the circuit and set? Using the coils mentioned and a .001 variable condenser I can just reach 485. How can I get the higher waves that are going to be assigned?—W. H. McKee, Wynn, Ark.

You can very easily overcome the trouble that you anticipate by substituting larger coils, preferably No. 100 and 75 DL or honeycomb coils. This will enable you to reach to all the wave lengths that will be assigned under the new regulations. You can very easily do this by simply connecting the new coils in the circuit.

* * *

I note that there is a new law going into effect to stop amateurs working their sets between the hours of 7:30 and 10:30 P. M. Does this mean that we will not be able to use our receivers between these hours or does it only affect the amateurs that hold Government licenses?—Henry Herbert, 569 West Street, Hoboken, N. J.

The new regulation means that amateurs owning transmitters will not be able to use them between those hours. This is to eliminate any interference between the broadcasters and the amateurs. It means that the broadcasters will have clear air between those hours.

Radio Left No Record

Barrister: But couldn't you let me have some of his love letters?

Breach of Promise Client: There weren't any. We had wireless sets.—*London Answers.*

Audio-Frequency Amplifier Unit for Simple Radio Receiving Set

VERY simple radio receiving outfits are described in a series of circulars issued by the Bureau of Standards of the Department of Commerce, and published at the request of the States Relation Service of the Department of Agriculture. The circulars are fully illustrated.

The first two, which are Bureau of Standards Circulars Nos. 120 and 121, describe receiving sets using crystal detectors. Circular 120 describes the receiving antenna and ground connection also. Circular No. 133 describes an electron tube detector unit which can be substituted for the crystal detector in either of the two sets previously described. Circular No. 137 describes telephone shunt and series antenna condensers and a loading coil for use with the simple receiving sets.

The fifth circular of this series is No. 141. It describes an audio frequency amplifier unit of such proportions that in external appearance it matches the electron tube detector unit. One or two of these amplifier units may be used with the equipment previously described to amplify the signals detected by the electron tube detector unit, or the detector unit may be omitted and one or two amplifier units used with the crystal detector. In either case the addition of the amplifier units results in a considerable increase of the volume of the received signal and increases the receiving range somewhat.

Copies of these circulars may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C. The price of Circular 141 is ten cents. The others are five cents.

How Religious Services Are Broadcast *By C. H. Huntley*

HAVE you ever wondered how a radio broadcasting station with its fixed equipment manages to send out religious services weekly from churches many miles away from the sending station?

The operating staff of WGY, the Schenectady, N. Y., station of the General Electric Company, has so developed church service broadcasting that thousands of letters of appreciation are sent in from far and near. Furthermore, clergymen who were frankly skeptical at first of the value of broadcast religious services and who doubted that the dignity and beauty of these services could be conveyed through the air, now pronounce radio an invaluable aid.

The installation necessary for broadcasting the services of the Second Presbyterian Church, Amsterdam, N. Y., on a recent Sunday, is typical and will give the radio fan an idea of how it is accomplished.

In the church were four microphones, two of them spares for emergency use. One microphone and a spare were placed at the reading desk to get the words of the clergyman in scripture reading, prayer, sermon and announcements and a microphone and spare were hung above and in front of the choir and organ. These microphones or pick-ups were the only evidence to the congregation that the service it was hearing was going out to countless thousands many miles away. There is nothing in the church installation to distract the attention of the congregation from the service.

At one side of the church, hidden from view but in a position where he could follow the service, was stationed one of the WGY staff who switched the microphones on and off as the service progressed. If the minister was speaking his microphone was brought into the circuit and the choir microphone was switched off.

Two other operators were situated in an adjoining room where a portable control equipment had been installed. In this room one of the operators controlled the amplification of speech and music. The amplifying outfit consisted of two five-watt tubes, one 50-watt tube and other necessary apparatus. Sufficient amplification was used to overcome line noise on the 20 miles of telephone wire necessary to carry the electrical oscillations set up in the microphone to the control room of WGY in Schenectady, N. Y. The second operator in the side room was in constant communication by special land wire with the control room at WGY.

In the control room in Schenectady the church services were again amplified, this time on equipment which consisted of one five-watt tube and two 50-watt tubes. From this point the electrical oscillations passed to the power apparatus and were impressed on the modulator and oscillator tube going thence to the antenna and the air.

Between church and control apparatus the church service passed through three exchanges of the New York Telephone Company—the Amsterdam exchange, the Schenectady exchange and finally the exchange of the General Electric Company.

MAGNAVOX
Radio Products

R2 Magnavox Radio *The* Reproducer Supreme

The Utmost in Sound Amplification

Where the reproduction of broadcasted programs is desired in large volume, the Magnavox Reproducer R2 should be used.

Thanks to the Magnavox (electro-dynamic) principle of construction, this result is secured with minimum electrical energy.

Without Magnavox equipment, no Radio receiving set is complete.

Magnavox R3 Reproducer and 2 stage Power Amplifier . . . **$90.00**

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field **$60.00**

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . **$35.00**

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

Can't Copy This Circuit

A NEW receiver which has a remarkable circuit that cannot be imitated has been perfected by the Atlantic & Pacific Radio Company, New York City. This receiver is so constructed that if taken apart the circuit is entirely destroyed. This makes the new circuit incapable of being copied, as its method of construction does not permit it.

The receiver is very selective and sensitive, having a range of 1,000 miles using one of the dry cell tubes. All connections are plainly marked and ample binding posts conveniently located are provided.

(C. Photonews)

A new uni-control receiver which cannot be examined or taken apart without destroying the circuit.

It is a single control set and operates with extreme clearness and sharpness of tuning. The entire set, with the exception of the batteries, encompasses a space of only 2x6x8 inches.

Variation to the Nth Degree

A NEW grid leak recently brought out by the Arthur Pudlin Engineering Company, 1540 Broadway, New York City, has several merits that would pay the up-to-date builder to investigate if he wants fine variation in grid leaks. The apparatus is a small bakelite tube with metallic ends, facilitating mounting in the various types of condensers that are made for use without combining grid leaks. Inside this tube is a special composition. A small wire with a handle projecting from one of the ends enables the user to obtain infinite variations and, as this is what is really needed, it should meet with a great demand by radio users and builders. It is either furnished complete with a grid condenser and mount, or by itself.

Radio Stocks

Series Parallel Switch for Panel Mount

THE Marvel Switch Company, 28 West 25th Street, New York City, have recently put on the market a new type of series-parallel switch which is small and unique in construction. Inasmuch as it is small and is meant for panel mount, it should furnish the builders of sets with an easy solution of series-parallel condenser connections. The entire switch is very little larger than the conventional knob. There are three positions marked on the switch, with a marker and stop for each position. The series and parallel positions are made by means of two double arms on four points, and a comprehensive drawing comes with each switch, enabling the user to make the connections easily and quickly. By drilling a few holes, for which the plate of the switch can be used as a template, the switch can neatly be mounted on the panel.

New Radio and Electric Firms

Park Auto and Radio Supply Corp., New York City, $5,000; I. Teitelbaum, B. and J. Bluestein. (Attorney, B. Indigo, 299 Broadway.)

Selko Electric Co., Brooklyn, N. Y., $10,000; J. Selikowitz, E. L. Braverman, S. H. Feinson. (Attorney, J. Feinson, 299 Broadway.)

Experimenter Publishing Co., New York City has increased its capital stock from $15,000 to $250,000.

Jenick Electric Co., New York City, general contracting. $5,000; A. and E. Jenick, P. Arnold. (Attorney, M. Remson, 342 Madison avenue.)

Far-Wes-Ton Electric Co., Jamestown, N. Y., $25,000; L. D. Norton, W. C. Westerman, C. E. Farren. (Attorney, H. R. Lewsi, Jamestown.)

Whiteland Radio Co., Brooklyn, N. Y., $50,000; J. L. Spence, J. Hoyt.

New List of Boys' and Girls' Summer Camps

FOLLOWING is a list of names and addresses of directors of boys' and girls' summer camps, each of whom should be a potential purchaser of radio sets for camp and vacation use. Additions to the list will be published in succeeding issues of RADIO WORLD:

Miss Gertrude Wood, Box 416, Maplewood, N. J.
Miss Corinne B. Arnold, 1419 Master St., Philadelphia, Pa.
G. L. Meylan, M.D., Columbia University, New York.
Miss L. Juliette Meylan, 468 West 141st St., New York.
G. L. Meylan, A.M., M.D., Columbia University, New York.
Arnold M. Lehman, 311 West 94th St., New York.
Abraham Mandelstam, 230 West 107th St., New York.
Sumner R. Hooper, Rockwood, Me.
Frederick L. Guggenheimer, 36 West 68th St., New York.
Hubert, L. Rand, 21 Heminway Rd., Salem, Mass.
P. H. & R. H. Cobb, Denmark, Me.
Frederick H. Wilson, M.D., Kingsley School, Essex Falls, N. J.
Frank D. Smith, 353 East 163d St., New York.
H. W. Gibson, 167 Tremont St., Boston, Mass.
Mrs. Sarah B. Hayes, Ashland, Mass.
Ralph C. Hill, Utica (N. Y.) Country Day School
Walter Overton, Camp Bob White, Ashland, Mass.
Mrs. Dwight L. Rogers, 8 Parkside Rd., Providence, R. I.
Dwight L. Rogers, Jr., Mountain Ave., Westfield, N. J.
Miss Lillian Millhauser, 220 West 110th St., New York.
Arthur W. Millhauser, 52 Broadway, New York.
Catherine E. Morrison, Ward-Belmont, Nashville, Tenn.
Emma I. Sisson, Ward-Belmont, Nashville, Tenn.
Mrs. Morris Stark, 925 West End Ave., New York.
James E. Harvey, 1807 Riggs Pl., N. E., Washington, D. C.
M. A. Harvey, 1807 Riggs Pl., N. E., Washington, D. C.
Miss Lucile R. Ryttenberg, 5 West 65th St., New York.
Eugene H. Lehman, Highland Manor, Tarrytown, N. Y.
Mrs. Madaleine D. Lehman, Highland Manor, Tarrytown, N. Y.
Miss Estelle B. Davidsburg, Highland Manor, Tarrytown, N. Y.
Helen C. Culin, Ogontz, Pa.
Irving G. McColl, Hotel McAlpin, New York.
Mr. and Mrs. G. R. Branch, 64 Fruit St., Worcester, Mass.
Mrs. Charlotte V. Gulick, South Casco, Me.
Miss A. R. Webster, 1325 Cypress St., Cincinnati, Ohio.
G. W. Rieger, Jr., 1103 Harrison St., Philadelphia, Pa.
F. Helen Mays, 16 Montview St., Boston 32, Mass.
Miss Clara Henderson, 1619 Eutaw Pl., Baltimore, Md.
Miss Mary North, 77 Orange Rd., Montclair, N. J.
Orrin J. Dickey, Belfast, Maine.
G. Rodman Bouck, 830 Yale Station, New Haven, Conn.
Roy E. Adams, 11 Marlborough Rd., Millbourne, Philadelphia.
Price B. Engle, 4699 Castor Rd., Philadelphia, Pa.
Arthur M. Condon, Northampton, Mass.
Dr. W. A. Keyes, 139 West 91st St., New York.
Eugene Hayden, North East Carry, Me.
H. J. Storer, Sec., 74 Fayette St., Cambridge, Mass.
Dr. M. Thorner, 2672 Boulevard, Jersey City, N. J.
H. B. Handy, 2218a Grove Ave., Richmond, Va.
Whitman G. Stickney, M.D., Beverly, Mass.
Carle O. Warren, 55 Hanson Pl., Brooklyn, N. Y.
A. H. Smith, 161 Albemarle St., Springfield, Mass.
N. Y.
Miss Laura I. Matoon, Jackson Hts., Elmhurst, N. Y.
George Ann Lillard, 5329 Kenmore Ave., Chicago, Ill.
Miss Helen Keyes, 144 Whiteford Ave., Nutley, N. J.
Miss Dora W. Eastman, Northampton, Mass.
Miss Elaine G. Eastman, Northampton, Mass.

Dr. Dudley A. Sargent, Cambridge, Mass.
Carl L. Schrader, 58 Payson Rd., Belmont, Mass.
L. W. Sargent, Sargent School, Cambridge, Mass.
Miss Jennie B. Wilson, 16 Oxford St., Cambridge, Mass.
Mrs. Mary G. Frick, 559 West End Ave., New York.
Miss Anna W Coale, Hotel Earle, 103 Waverly Pl., New York.
Miss Mary Arabella Coale, 323 W. 83d St., New York.
F. W. Luehring, University of Minnesota, Minneapolis, Minn.
Mrs. M. R. Wolfard, Cambridge, Mass.

(*Continued in next column*)

Alice A. Kranz, 745 Riverside Drive, New York.
Henry S. Pettit, 106 Gates Ave., Brooklyn, N. Y.
Miss Gertrude Bilhuber, Maywood, N. J.
Miss Ida B. Post, 509 W. 121st St., New York.
Miss Eleanor Deming, 945 West End Ave., New York.
Miss Agathe Deming, 945 West End Ave., New York.
Miss Josephine Cowhey, 1061 St. Nicholas Ave., New York.
Miss Jeannette Frank, 529 West 179th St., New York.
Mr. and Mrs. M. Gordon, 854 West 180th St., New York.
Mr. Joseph Lowe, 13 Astor Place, New York.
Mrs. L. Schwarzkopf, 611 West 158th St., New York.
Dr. Henry S. Pettit, 106 Gates Ave., Brooklyn, N. Y.
Miss Marcia C. Noyes, 1211 Cathedral St., Baltimore, Md.
M. L. Fielding, 776 Hewitt Place, New York.
E. E. Lyons, 251 Smith St., Brooklyn, N. Y.
Bertha Lipstein, 5000 15th Ave., Brooklyn, N. Y.
Rev. J. R. Sevier, D.D., First Presbyterian Church, Augusta, Ga.
Mrs. Sevier.
Miss Evelina Reamley, 12 Beacon St., Gloucester, Mass.
Miss Florence E. Griswold, 313 Hope St., Providence, R. I.
John B. May, M.D., Cohasset, Mass.
Ethan Allen Shaw, Northfield, Vt.
Mrs. A. C. Fontaine, Roslyn Heights, N. Y.
Andre C. Fontaine, Roslyn Heights, N. Y.
Mother M. Loretta, R. S. U., Ursuline Convent, Middletown, N. Y.
Miss Kate B. Wallace.
Miss Theoda F. Bush, Dana Hall School, Wellesley, Mass.
Ray K. Phillips, 949 Broadway, New York.
Adolph Black, 3905 Broadway, New York.

(*To be continued*)

Radio Limericks

(*Silly little things we call 'em, but they amuse a light-hearted world. Send us your limerick, with name and address.*)

There was a housemaid of Elmira,
And naught in the U. S. would tire her.
'Til a radio set caught her fast in its net—
And she loafed 'til the folks had to fire her.
—F. P. Marsden, Madison, Wis.

I am a young fellow of Philly,
Who, although you may say I am silly,
Can build an antenna, and work it, and then a
Cop brings it down with his billy.
—James B. Skoon, Philadelphia, Pa.

There was a smart girl of Canarsie,
Bought a radio set to let pa see.
She got lost in the ether above and beneath her,
And father said: "Don't go too far—see!'
—Jack S. Palmer, Portland, Me.

"And the Mules Came Back"

WHILE in Atlanta, Ga., recently on a radio inspection trip Commissioner Carson, of the Department of Commerce. was advised that his best team of mules had disappeared from his farm in a nearby state, and, being later in the broadcasting station of a local paper, he let their loss be broadcast with a description. A few days afterwards when in Nashville, Tenn., he was advised that his mules had been found wandering miles from home. Whether radio was responsible for their discovery or not cannot be proved, the commissioner says, but he believes it was instrumental in their release from temporary confinement. "I was glad to get them back," he added. "They were good mules."

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Summer Park Concerts to Be Broadcast

ALTHOUGH the broadcasting of the government's band concerts by NAA, Arlington, will cease during the summer months, radio fans within several hundred miles of Washington, D. C., will be able to pick up some concerts if the plans of the Chesapeake and Potomac Telephone Company are carried out.

By June 15 this company hopes to complete its new station in Washington and start broadcasting the open-air public concerts from the White Lot and local parks, where the marine, navy and army bands will play almost daily.

Through the aid of a new portable "input apparatus," recently perfected by the telephone engineers, the C. & P. company expects to furnish the added "juice" necessary to pick up concerts and transmit them by wire to their station for radio broadcasting. This apparatus is mounted on a motor truck, and can be dispatched anywhere in the city where something is to be broadcast.

Representatives of the company say that it is also sometimes difficult to relay speeches and music from private residences via telephone lines to broadcasting stations, due to lack of current, but with the new "booster" they expect to overcome this handicap.

Important speeches and some concerts will also be put on a land line to New York and broadcast simultaneously from WEAF on a different wave length.

Most of us still prefer the telegraph. They don't send bedtime stories over that.—*Wall Street Journal.*

RADIO BROADCASTING MAP

FOR the benefit of those interested in Radio and those who are becoming interested, Rand McNally & Company have prepared a publication containing a wealth of information of greatest value. It shows in the most comprehensive way, the location of the broadcasting stations, gives their classification, the call letters, wave lengths, ownership, etc., of each.

The Rand McNally Radio Map of United States is 28x30 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover.

WOR Opens Its New Studio

AT eight o'clock on the evening of May 10 L. Bamberger & Company's radio broadcasting station, WOR, at Newark, N. J., was officially opened for use. The new studio is located on the main floor at the Bank street entrance of their store.

Instead of the common practice of having just one large studio this station now has two. One is a room forty feet long and thirty feet wide, hung with heavy gray draperies and furnished with heavy rugs.

In this studio will be accommodated all the large bands, dance orchestras, singers—in fact, every program that requires a spacious place to produce good results.

Adjoining this main studio is another one, much smaller, which is to be used in broadcasting speeches and programs not necessitating the use of the larger room. It is furnished in the same manner as the other, but is deadened even more than the larger one. Across the hall is the reception room, where the artists and guests can gather before the program.

This station has accomplished some wonderful work in the past; but, with the aid of the newer and larger quarters and increased facilities, everything will be easier to handle, and, therefore, better results will be produced.

The Future of Radio Visualized

C. FRANCIS JENKINS, of Washington, D. C., delivered an address on "Radio Photography, Movies and Vision," before the annual convention of the Society of Motion Picture Engineers last week at Atlantic City, N. J.

"No newspaper can possibly put a distant news event before the public as quickly as the theatre can with radio pictures," he said. "It is possible, perhaps probable, that a news bulletin in pictures and type may be broadcast and the photographic negative thereof be used in the printing of the usual news bulletin sheet either by direct photographic process or by a photo-etching process, the etched plate for use in the printing press. This would eliminate the necessity of local typesetting plants.

"The police departments of the various cities of the country would also doubtless be customers for picture distribution service, as photographs of criminals, as well as their thumb prints could be readily distributed. Bankers and business executives could in a few minutes verify signatures to checks, drafts or documents; indeed contracts and other forms of credit could be exchanged across the continent within the hour."

Music Publishers Give in to Broadcasters

Radio World's Suggestion That Broadcasters Are Able to Popularize Their Own Music Helps to Bring About a Quick Showdown

THE Music Publishers' Association of the United States, following the recent announcement in RADIO WORLD that broadcasters could popularize their own music, has helped to solve the situation satisfactorily. A few days ago, the Music Publishers' Association agreed to permit the broadcasting, without fee, of the music controlled by their members, at least temporarily.

The members of the Association are perfectly well aware of the fact that the broadcasters, following the suggestion of RADIO WORLD and the lead of the Westinghouse Electric and Manufacturing Company in cutting out all copyrighted music from their broadcasting programs, solved the situation, and made it necessary for the Association to come to terms immediately or lose the tremendous advertising possible through broadcasting. At the meeting of broadcasters held recently in Chicago, certain strenuous lines of action were decided upon. This combination of circumstances made the publishers see a strong light.

M. E. Tompkins, of G. Schirmer, Inc., New York, publishers, chairman of the committee, in a statement said: "Our Association, which has been in existence since 1895, represents particularly the so-called 'standard' publishers, which make up a majority of its forty-nine members, as distinct from publishers of popular music, although a number of the latter are also members.

"Our committee has been carefully investigating the broadcasting of copyrighted music since last November. In our report, just adopted by the Association, we point out that music publishers are vitally interested in radio broadcasting as a great future user of music and that our rights in the use of our copyrighted music in public performances must be protected. However, we appreciate the fact that radio broadcasting is still in a chaotic and experimental state and that, while ultimately it will have to be placed on a commercial basis if it is to develop its potentialities, nevertheless the commercial side of the broadcasting problem has not yet been solved.

"In view of these facts and also because we desire to cooperate in developing the music possibilities of radio, we believe that we should allow the use of our copyrighted musical compositions for broadcasting without charge for the present, and without prejudice in our rights."

While the action of the Music Publishers' Association does not bind its members, but merely recommends, it is understood that most of the large standard publishers in its membership will follow the recommendations of the Association. The following representative standard publishers have definitely decided to follow the recommendations: Carl Fischer, G. Schirmer, Inc., C. H. Ditson Company, John Church Company, Boosey & Company, and Hinds, Hayden & Eldredge of New York City; Oliver Ditson Company and B. H. Wood Music Company of Boston; Paul A. Schmitt of Minneapolis and Clayton Summy of Chicago.

The Producing Managers' Association, of New York, has lined up with the music publishers and is in favor of releasing copyrighted music to broadcasters without demanding fees. This was demonstrated by Arthur Hammerstein, as chairman of the managers' committee on radio, which has been looking into the subject for a month.

"We are not at all averse to the broadcasting of our music by radio," he declared. "In fact, we are very much for it. We believe in letting the public hear the scores in our productions. It's good advertising, and is a strong boost for business.

"It is the composer who is protesting against the use of the music, and on what grounds I haven't been able to figure out. To begin with the music is the property of the producer. He purchased it and has a right to let it be broadcast if he wants to. As it happens, we all do want to." Accordingly, the radio committee of the Producers' Association will take steps to open the music of the various shows to the broadcasting stations without charge.

Cockaday Circuit

Pointers You Should Know When Installing

A FEW pointers regarding the installation of the receiving set should prove valuable for every one who owns a radio set. As a matter of fact one need pay little attention to the installation of the simple sets, for the reason that their simplicity limits their efficency, so that finer details of installation hardly apply to them. When it comes to elaborate vacuum tube receiving sets, it may be well to give a little thought to the installation for the purpose of obtaining the utmost efficiency. So says the New York "Globe," and continues:

To begin with the receiving apparatus should be placed so as to permit the shortest possible leads from the receiving where the lead-in enters the room. The lead-in should be short as possible. Sufficient space should be provided between the instruments and the desk of operating table so as to make easy the manipulations of the receiver.

The antenna leading from the lightning switch should pass through an insulator when coming through the wall and the ground wire, which is number 14 rubber-covered copper wire, should be brought in very carefully. With all these in mind we should be able then to check up our weakness elsewhere should we have the occasion to do so.

SHORT CUT

Replaces aerials, loops, electric light plugs, etc. Brings clearer signals and truer tone.

Postpaid $5.00

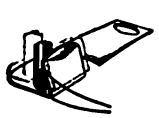
Na-ald Special Socket No. 499



Na-ald De Luxe No. 498

It's the contact that counts

The dual-wipe contact strips of the Na-ald De Luxe socket avoid the trouble experienced with the socket of conventional design. Because of thorough cure and high dielectric properties this socket keeps plate to grid losses at a minimum (of particular importance in Flewelling Circuit or in Radio Frequency).

Price 75 cents

The Na-ald Special Socket No. 499 is a sturdy little socket for the G. E. No. 199 dry-cell tube. It has special slot construction, and is moulded of genuine Bakelite. The heat from soldering connections will not affect these sockets.

Price 50 cents

Booklet with wiring design and instructions for Hazeltine's Neutrodyne circuit, together with other selected circuits, packed with each Na-ald product or sent in exchange for cover taken from any Na-ald carton.

Old WJZ Signs Off For The Last Time

WJZ signed off—for the last time. Station closed down. All's Well"

The operator in charge made this entry in the station log book of WJZ, Newark, N. J., on the night of May 14. It was his last official act. They had ordered away not only his outfit but even his call letters. Old WJZ passed out of the broadcasting firmament in military fashion—quickly, quietly and with dignity.

"Broadcast Central," on top of Aeolian Hall, New York City, inherited the call WJZ and began operations the next night with shiny, new, strictly up-to-the-minute equipment. The juggernaut of progress knows no sentiment.

There are radio fans who swear by old WJZ. It was the first station that many of them ever heard, their ABC in radio broadcasting. WJZ led the field for one and a half years. This is a long life for a broadcasting station, and in that time many others have been built and operated. When WJZ began its first famous broadcast on October 12, 1921, there were only three or four stations broadcasting throughout the land. Today, there are about 600, but in spite of this immense increase WJZ has held its own and in many ways has blazed the trail.

Old WJZ enjoys the distinction of being the first broadcasting station to have its complete program published by a metropolitan newspaper. Lately, over 1,100 newspapers in the United States and foreign countries published the WJZ program.

WJZ could claim a transmitting radius of 2,000 miles. It was heard almost nightly in California and in England. It had followers in Australia, Cuba, South America and Europe. On one occasion, its signals were heard simultaneously in Honolulu and Bremerhaven, Germany, some 10,000 miles!

Mr. William H. Easton, retiring director, made a little farewell speech which was broadcast just before WJZ closed down. He concluded by saying:

"We shall never forget you of the radio audience and we trust that no matter how wonderful the new WJZ may be, you will never forget the first to bear that name. In behalf of the Westinghouse Company, I want to thank you for the splendid cooperation you have given us. I want also to thank the artists who have honored this station with their presence and who have given to you the best of the world's music and thought. And finally, I wish to thank our fellow broadcasting stations for the friendly spirit they have shown us at all times. The Westinghouse Company is not giving up broadcasting, as it will continue the operation of KDKA, Pittsburgh; KYW, Chicago; and WBZ, Springfield. But the voice of WJZ, Newark, N. J., is to be stilled forever. Well, good night, friends—and goodbye!"

From Near the Equator to Schenectady

WGY was recently picked up by the steamship Ebro of the Pacific Steam Navigation Company when one day out from the Juan Fernandez Island, west of Valparaiso, Chili, about 5,400 miles from Schenectady, N. Y., the home of the General Electric Company broadcasting station. Information of the long distance reception was contained in a letter from W. F. Robertson of Cincinnati, Ohio, who was a passenger on the boat. Mr. Robertson stated that the ship's radio operators were using his set.

WGY has been heard greater distances than Mr. Robertson reports, but reception has never been reported as far south as the Juan Fernandez Islands. The distance is remarkable because of the heavy interfer-

DO YOU WANT TO BUY, SELL OR EXCHANGE RADIO OR OTHER GOODS? TRY THIS DEPARTMENT AT 5c A WORD

RADIO WORLD'S QUICK-ACTION CLASSIFIED ADS

This department is intended for everybody who wants quick action on short announcements covering the buying, selling exchanging or general merchandising in the radio field. Readers of RADIO WORLD will find that it pays to read these columns every week. Advertisers will get a ten-day service here—that is, copy received for this department will appear in RADIO WORLD on the news-stands ten days after copy reaches us.

The rate for this RADIO WORLD QUICK-ACTION CLASSIFIED AD. DEPT. is 5c. per word (minimum of 10 words, including address), 10% discount for 4 consecutive insertions, 15% for 13 consecutive insertions (3 months). Changes will be made in standing classified ads. if copy is received at this office ten days before publication. RADIO WORLD CO., 1493 Broadway N. Y. C. (Phone, Bryant 4796).

BROADCASTING OUTFIT using five fifty watt tubes to be sacrificed. Everything complete. Make us an offer. Park City Radio Company, Bowling Green, Ky.

FOR SALE—Two Myers Choke Coils, 8 Myers tube receptacles, three Cot-o-Coil Radio Transformers, all for $15.00. F. T. Lesser, 85 Lincoln St., Ridgway, Pa.

TO THE WIDE-AWAKE! Are you in need of a ribbon for your typewriter? And do you have it handy? Shoot me 50c and I'll send you one. Actual value paid for sick, out-of-order typewriters; if visible or invisible. The men and women of today must have Standard machine. Send for one—any make. Busy B Service. Information on request. John A. Hendrikson, 367 Chicago Ave., Chicago, Ill.

FOR SALE—Twin variometer set with antenna condenser and potentiometer. Two step amplifier in same oak cabinet—specially built for touring. $75.00. Tubes, Batteries, and Baldwin type C Phones, $35.00. One two step amplifier, $20.00. One two step amplifier, $15.00. One Radio Flivver with tube, $17.50. DAVID L. THOMPSON, 766 Kalamath St., Denver, Colo.

MEN AND BOYS, get all the inside information on Radio. Radio Guide, also diagrams and blueprints for home construction aerials, inlaid Radio cabinets. Everything to your electrical knowledge. If interested, write, please. John A. Hendrikson, 367 Chicago Ave., Postal Subs., Chicago, Ill.

CHEAPEST TO BUILD—Easiest to tune. Get particulars Rokay Single Control Hook-up. Describe your set. Rokay Electric Company, Ingomar, Ohio.

HYPNOTISM—Controls self and others. Wants gratified. Ten easy methods, $1.10. "MIND-READING" (any distance)—Wonderful, $1.10. SCIENCE INSTITUTE, RW 1014 Belmont, Chicago.

CRAM'S RADIO BROADCASTING MAP of the UNITED STATES & CANADA. Scale 100 miles to the inch. In two colors, size 34x28. Printed on high-grade map paper, up to-the-minute information, indicating all amateur and standard broadcasting stations, with complete index to stations. 35c postpaid. The Columbia Print, 1493 Broadway, N. Y. C.

OLD MONEY WANTED—$2.00 to $500.00 **EACH** paid for hundreds of Old and Odd Coins. Keep all old money. Send 10 cents for New Illustrated Coin Value Book, 4x6. You may have valuable coins. Get posted. We pay CASH. CLARKE COIN COMPANY, Ave. 83, Le Roy, N. Y.

AUTOMOBILE REPAIRING MADE EASY—By Victor W. Pagé. A thoroughly practical book containing complete directions for making repairs to all parts of the motor car mechanism. Written in a thorough but non-technical manner. Gives plans for workshop construction, suggestions for equipment, power needed, machinery and tools necessary to carry on business successfully. Tells how to overhaul and repair all parts of all automobiles. The information given is founded on practical experience, everything is explained so simply that motorists and students can acquire a full working knowledge of automobile repairing. Other works dealing with repairing cover only certain parts of the car—this work starts with the engine, then considers carburetion, ignition, cooling and lubrication systems. The clutch, change speed gearing and transmission systems are considered in detail. Contains instruction for repairing all types of axles, steering gears and other chassis parts. Many tables, short cuts in figuring and rules of practice are given for the mechanic. Explains fully valve and magneto timing, "tuning" engines, systematic location of trouble, repair of ball and roller bearing, shop kinks, first aid to injured and a multitude of subjects of interest to all in the garage and repair business. This book also contains Special Instructions on Electric Starting, Lighting and Ignition Systems, Tire Repairing and Rebuilding, Autogenous Welding, Brazing and Soldering, Heat Treatment of Steel, Latest Timing Practice, Eight and Twelve-Cylinder Motors, etc., etc., You will never "Get Stuck" on a Job if you own this book. 1,000 specially made engravings on 500 plates. 1,056 pages (5½x8). New Edition. Price

THREE NEW 50 WATT TUBES. Never used. $20 each. W. N. A. B., Bowling Green, Ky.

FREE CATALOGUE. Ebonite panels, 7x12, 50c.; 23 plate variable condensers, $1.25; American No. 200 Tubes, $3.00; Amplifying, $3.75; W. D. 12 Peanut, $5.75; Sockets, 25c. Stewart's Radio Supply Co., 3124 Cherokee St., St. Louis, Mo.

BUILDERS AND EXPERIMENTERS. Do you know that the Reflex circuit is one of the most interesting circuits to construct? You can not guess how much fun you are missing if you fail to try out at least one of these circuits. See RADIO WORLD issues of Feb. 24 and March 3. They contain two fine articles by W. S. Thompson, with plenty of new Reflex circuits to experiment with. Don't miss these! 15c. a copy. RADIO WORLD, 1493 Broadway, New York City.

CASH FOR OLD GOLD, Platinum, Silver, Diamonds, Liberty Bonds, War, Thrift, Unused Postage Stamps, False Teeth, Magneto Points, Jobs, Any Valuables. Mail in today. Cash sent, return mail. Goods returned in ten days if you're not satisfied. OHIO SMELTING CO., 337 Hippodrome Bldg., Cleveland, Ohio.

A WONDERFUL CRYSTAL SET. Can hear all over Philadelphia, and sometimes outside of Philadelphia. Price with phones, $12.00; without phones, $6.00. Receiving sets, $35 to $200. Guaranteed or money back. Send Money Order or call. Williams Radio, 2339 N. 8th St., Philadelphia, Pa.

SUPER-SIMPLICITY CIRCUIT—1,000 to 1,500 miles on one tube, one control, 150 to 20,000 meters. No rheostat, storage battery, vario coupler, variometer, 3-coil mounting, variable industance, taps or radio frequency. Nothing to guess about. Complete hook-up and particulars, $1.00. No checks. Build your own. Save 90% and get better results. RADIO EXPERIMENTAL LABORATORY, Box 194A, Berkeley, Calif.

WOULD YOU LIKE TO RECEIVE RADIO LITERATURE? Are you in the market for radio goods of any kind, either as a consumer, a distributor or a retailer? If so, send us your name and address on a post card and we will see that your name reaches the right people so that you will receive pamphlets, circulars, etc., regarding the goods you want. Address SERVICE EDITOR, RADIO WORLD, 1493 Broadway, New York City.

ELEMENTS OF RADIO TELEPHONY, by Wm. C. Ballard, Jr. A standard book on radio telephony, the work of a recognized authority. Accurate, simple, clear, reliable and strictly up-to-date. For the technical man who wants to post himself on radio and for the radio enthusiast who wants the fundamental principles of radio and their application tersely and entertainingly presented. Price, postpaid, $1.50. The Columbia Print, 1493 Broadway, New York.

WIRING A HOUSE. By Herbert Pratt. Shows a house already built; tells just how to start about wiring it; where to begin; what wire to use; how to run it according to insurance rules; in fact, just the information you need. Directions apply equally to a shop. Sixth edition. COLUMBIA PRINT, 1493 Broadway, N. Y. C. Price, 35 cents.

EXCHANGE JOLLY, INTERESTING LETTERS through our club. Stamp appreciated. Betty Lee, Inc., 4254 Broadway, New York City

MOTOR BOATS AND BOAT MOTORS—By V. W. Pagé and A. C. Leitch. All who are interested in motor boats will find this latest work a most comprehensive treatise on the design, construction, operation and repair of motor boats and their power plants. It is really two complete books in one cover, as it consists of two parts, each complete in itself. Part one deals with THE HULL AND ITS FITTINGS, part two considers THE POWER PLANT AND ITS AUXILIARIES. A valuable feature of this book is the complete set of dimensioned working drawings detailing the construction of five different types of boats ranging from a 16-foot shallow draft, tunnel stern general utility craft to a 25-foot cabin cruiser. It is a comprehensive work of reference for all interested in motor boating in any

Reinhold Radio Detector. A CHEMICAL DETECTOR. Every spot equally sensitive. Lasts indefinitely. Permanent graphite contact. Ideal for reflex circuits. $1.50 prepaid. WARRENDARCY RADIO COMPANY, 1441 Broadway, N. Y.

MAKE YOUR OWN storage "B" batteries. RECTIFIER and D. C. recharger. BLUE PRINTS $1. S. Marchese, P. O. Box 417, Brooklyn, N. Y.

ARE YOU IN THE RADIO BUSINESS? If so, drop us a card for price list. If not, let us start you in a good paying business. We furnish everything and have a proposition that meets the needs of 90% of the public. Liberal discounts to agents. Immediate delivery. Write today. THE WILKENDA COMPANY, 500 Fifth Avenue, New York.

VACUUM TUBE RESULTS FROM A CRYSTAL SET! A "PT" Ultra-Sensitive Contact will increase the range and audibility of your crystal set. We guarantee this wonderful Contact to be MORE SENSITIVE THAN ANY OTHER CAT-WHISKER MADE; and that IT WILL NOT JAR OUT. WITH A "PT" MYRLE WOOD HEARD 46 PHONE STATIONS, IN A THOUSAND-MILE RADIUS! Others likewise testify that the "PT" has given results equaling tube equipment. Simple to install in any crystal detector. Price only twenty-five cents coin. "PT" CRYSTAL CONTACT COMPANY, Box 1641, BOSTON.

Build your sets with quality parts and get sure results. Radio Parts Co., Box 56, Dunellen, N. J.

PATENTS—SEND DRAWING OR MODEL FOR EXAMINATION AND OPINION. Booklet free. Watson E. Coleman, Patent Lawyer, 624 F Street, Washington, D. C.

EXCHANGE LETTERS with friends everywhere. Pleasant pastime. Information for stamp. Smith, Box 3125, M. Portland, Ore.

RADIO FANS AND PROFESSIONALS—How many of you know the correct CODIFICATION of all characters, punctuations and signs (such as $, %, etc.). We dare say that nine out of ten don't know them correctly! Our instructor who has had 35 years experience, eight years of which were with Uncle Sam as MORSE and RADIO TELEGRAPHER, has just published the first and only CHART known to give fully a true and correct CODIFICATION of ALL characters used in both codes. This CHART is indispensable to all up-to-date beginners and veterans alike. Fifty cents (money order preferred) will bring CHART, also much information extremely interesting to BOYS and GIRLS; because, with this information and a little PEP on your part, you can qualify shortly (as scores of our graduates have done) and secure positions paying $1,500 to $3,000 yearly. (See Civil Service Bulletins 215, 157 and 54.) We are registered with the U. S. C. S. Com. at Washington and can help you. AMERICAN TELEGRAPHIC STUDIO, BOX 793, WORCESTER, MASS.

TWENTIETH CENTURY BOOK OF RECIPES, FORMULAS AND PROCESSES—Edited by Gardner D. Hiscox. This book of 800 pages is the most complete book of recipes ever published, giving thousands of recipes for the manufacture of valuable articles for every-day use. Hints, helps, practical ideas and secret processes are revealed within its pages. It covers every branch of the useful arts and tells thousands of ways of making money and is just the book everyone should have at his command. The pages are filled with matters of intense interest and immeasurable practical value to the photographer, the perfumer, the foundryman, the machinist, the potter, the tanner, the confectioner, the chiropodist, the manufacturer of chemical novelties and toilet preparations, the dyer, the electroplater, the enameler, the watchmaker, the jeweler, the ink manufacturer, the optician, the farmer, the dairyman, the paper maker, the metal worker, the soap maker and the technologist in general. A book to which you may turn with confidence that you will find what you are looking for. A mine of information up-to-date in every respect. Contains an immense number of formulas that everyone ought

Short Radio Waves Transmitted in Beam Like Searchlight Reduce Interference

WITH the development of radiotelephone transmitting apparatus the transmission of the voice or music broadcast by radio has assumed an important place in the radio field. Radio waves which are transmitting the voice or music occupy a wider band of wave lengths than a "sharp" wave transmitting radiotelegraph signals. Because of this great increase in a kind of service which requires a wide band of wave lengths there is already considerable interference among broadcasting stations, and between broadcasting stations and radiotelegraph stations.

These authorities state that, for point-to-point communication, there are two important ways of reducing such interference; that is, to direct the waves radiated from the transmitting stations in a narrow beam toward the receiving station, and to use short wave lengths which are not at present employed.

Some English investigators have recently reported on the results of their investigations on directive short-wave transmission.

Experiments have recently been conducted at the Bureau of Standards on transmitting apparatus employing electron tubes, which transmits a directed beam of radio waves, and employs waves as short as 10 meters. This system, therefore, offers substantial relief from interference difficulties. It also has possible military applications. The apparatus has been used for communication by both radiotelegraphy and radiotelephony.

In the experiments at the Bureau of Standards a reflector has been used consisting of short parallel vertical wires, arranged on a frame shaped like a parabola. This reflector acts much like an ordinary mirror would for light waves. The radio waves are, in fact, the same kind of waves as light waves, but of considerably longer length. Forty vertical wires were used, and the generating set with its small antenna was placed at the focus of the parabola. Each wire was tuned separately to 10 meters by adjusting its length. It was found that about 75 per cent of the radiated energy could be confined within an angle of about 75 degrees.

This apparatus is described in Scientific Paper No. 469 of the Bureau of Standards, entitled "Directive Radio Transmission on a Wave Length of Ten Meters," by F. W. Dunmore and F. H. Engel. Copies may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C. The price is 10 cents.

Opportunity for Radio Development in China

THE time seems ripe for radio broadcasting in China," says G. W. Van Tubergen, of the International Western Electric Co., who has just returned from that country. Radio should prove a distinct advantage to the Chinese people as those living in the small cities and villages even though only a few hundred miles from the larger cities are shut off from all direct contact with the larger life of their own country to say nothing of international happenings. Communication between villages is very restricted. It is literally by oxcart. And it is said that these places make up 90 per cent of China.

"It is very evident to those of us who daily enjoy the advantages of radio that these people living in the interior villages could have the privilege of listening to news reports, music, lectures and sermons and the like broadcast for them from Tientsin and

Radio Control in Great Britain

RECENT developments in England indicate that a strong effort will soon be made to relieve the amateur radio operator in that country from having to pay a proposed increase in license and buy his apparatus from the British Broadcasting Company. Radical steps to break the alleged monopoly are predicted, although they may not remove the bar against foreign manufactured radiotelephone sets. If development is to be permitted the whole situation must be simplified, many believe.

The new postmaster-general is said not to be especially sympathetic toward the present arrangement, but it is felt he will insist that apparatus be of United Kingdom manufacture. Many fans in Great Britain want to make their own receiving sets and utilize some manufactured parts. Today these radio fans can only secure an experimenter's license, but after receiving their permits they can use any kind of a set or part they desire, and listen in on all stations. These licenses, it is reported, remove them from the control of the British Broadcasting Company. It is assumed that they are engaged in experimental work, but they undoubtedly listen in on all broadcasting concerts.

The Radio Manufacturers' Association has suggested abandoning the present method of securing revenue for the broadcasting company by license fees and royalties, and collecting the amount necessary for adequate revenue from the license fee. Restrictions against the so-called "pirate" would then be tightened.

According to a statement in Parliament 35,383 experimental licenses have been issued, while as many more applications are on file. It is estimated that 200,000 individuals are using sets without licenses because they cannot secure the licenses they desire.

Studying Foreign Languages by Radio

SCHOOLS in Sheffield, England, recently had the privilege of listening to French prose and poetry broadcast from a French radio station. The director-general of the French Radio Service consented to cooperate with Mr. F. Lloyd, president of the Sheffield District Wireless Society, in an effort to provide for foreign language students the broadcasting of standard and classical foreign literature. It is hoped that this first-hand instruction can be extended to include the broadcasting of English, German, Italian and Spanish language lessons.

Summer Static Overcome

"Good-bye Aerial"

ANTENELLA

No aerial or antenna needed

All outside wiring, aerial, lightning arresters, switches and other inconveniences so inductive to static are eliminated.

Merely plug Antenella in any light socket and you can enjoy all Radio pleasures in any room in your home, apartment or hotel. No current consumed.

New Improved

ANTENELLA

NOW ONLY $1.25

formerly $2.00

PATENTS

To the Man with an Idea

I offer a comprehensive, experienced, efficient service for his prompt, legal protection, and the development of his proposition.

Send sketch or model and description, for advice as to cost, search through prior United States patents, etc. Preliminary advice gladly furnished without charge.

My experience and familiarity with various arts frequently enable me to accurately advise clients as to probable patentability before they go to any expense.

Booklet of valuable information, and form for properly disclosing your idea, free on request. Write today.

RICHARD B. OWEN, Patent Lawyer

Broadcasting in India

BROADCASTING in India will probably be limited to a single company, composed of British and Indian firms, according to a report of the recent Delhi conference forwarded to the Department of Commerce by Vice Consul Harold Shantz, Calcutta. Non-British firms will not be allowed to participate, it is said.

The Director of Wireless has pointed out that under the proposed license an imported set of apparatus would only be authorized if of British manufacture but that it would be permissible to buy parts from the United States or other foreign countries and assemble them in India. The director said that the proposed company would be essentially an Indian one, registered in India and with headquarters there.

It is understood that the manufacture of receiving sets is to be undertaken in India as soon as practicable by the new broadcasting company; this will probably at first consist of the importation of some parts, the local manufacture of others, and the assembling of complete sets.

In this connection it may be observed that at the present time no wireless equipment can be imported into India which is not for Government use, except under a special import license from the Director of Wireless, and by persons who are licensed to operate.

"Great Oaks from Little Acorns Grow"

In 1914 the Fuller Brush Company put aside $2,500 as an advertising appropriation. That year the company did a business of $256,860. Constant growth was enjoyed until 1922 when the advertising appropriation reached $434,871 and the business for the year amounted to $11,452,373. The cumulative effect of constant advertising is shown by the fact that at the beginning the amount of advertising expenditure was about one per cent of the annual sales, while last year the gross business was nearly five times as great as in 1914 and the advertising appropriation was less than one-half of one per cent of the yearly sales.

Advertising truths are beginning to be appreciated in the radio industry and among them is the one so often quoted: "Keeping everlastingly at it brings success."

Sometimes it requires nerve to make the plunge—but one soon learns to swim. Get the advertising started, prepare careful and compelling copy, keep faith scrupulously with customers the advertising brings and pretty soon advertising will earn its place in the radio field as its most valuable ally.

Radio Situation in Ireland

NO definite policy has been announced by the Irish Government up to date regarding its position with respect to wireless broadcasting, or the operation of private receiving sets. There is a small market for this class of equipment, which, since the regulations of the British Post Office and the British Broadcasting Company do not apply in Ireland, is open to foreign manufacturers.

THE BOY MECHANIC

700 THINGS FOR BOYS TO DO
480 Pages—700 Articles
800 Illustrations — Cloth
Price $2.00 Prepaid

The Ideal Book for the Wide-Awake Boy

All the things described in this volume have actually been built or experimented with by boys. The ideas contained in "The Boy Mechanic" would more than keep a boy occupied until he grows up and also be an incentive to original thinking and achievement.

The Most Interesting Boys' Book
Unlike so many other books of a somewhat similar nature, it is not confined to only one or a few subjects, but describes 700 different things boys can make and do in the fields of mechanics, electricity, sports, arts and crafts work, magic, etc.

An unusually generous book: size 7 by 10 in. and 1½ in. thick; printed from large, clear type on high grade book paper and durably bound in cloth. Attractive four-color cover design.

Wholesome, Practical, Instructive
Besides telling how to make scores of things useful about the house, full and complete directions are given for constructing hundreds of things which appeal to the heart of every boy.

Many hours of enjoyment are in store for the boy who becomes possessor of this book.

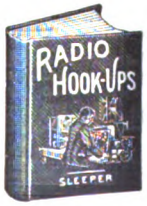
Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems

How to Make Commercial Type Radio Apparatus

By M. B. SLEEPER

This book describes in detail many commercial types of spark and vacuum tube telephone transmitting and telegraph and phone receiving equipment of all kinds. The experimenter will be able to get a world of ideas for the design and construction of his next piece of radio equipment from the very clear descriptions and the 98 clearly illustrated figures.....PRICE 75c.



Radio Hook-Ups

By M. B. SLEEPER

A book that gives you not only clear diagrams for all kinds of telephone and telegraph receiving and transmitting sets, but simple descriptions of each circuit shown and spaces for notes of results obtained.

PRICE 75c.

The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

Na-ald Special Socket No. 499

Na-ald De Luxe No. 400

It's the contact that counts

The dual-wipe contact strips of the Na-ald De Luxe socket avoid the trouble experienced with the socket of conventional design. Because of thorough cure and high dielectric properties this socket keeps plate to grid losses at a minimum (of particular importance in Flewelling Circuit or in Radio Frequency).

Price 75 cents

The Na-ald Special Socket No. 499 is a sturdy little socket for the G. E. No. 199 dry-cell tube. It has special slot construction, and is moulded of genuine Bakelite. The heat from soldering connections will not affect these sockets.

Price 50 cents

Na-ald Adapter for No. 199 tube, $1.00.

Booklet with diagram of Hazeltine's Neutrodyne circuit and other selected circuits packed with each Na-ald product or sent in exchange for cover taken from any Na-ald carton.

VOLUME THREE OF

RADIO WORLD

[Entered as second-class matter, March 28, 1922, at the Post Office at New York, N. Y., under the Act of March 3, 1879]

A Weekly Journal, Published Every Wednesday and Dated Saturday, by Hennessy Radio Publications Corporation from Publication Office, 1493 Broadway, New York, N. Y. Telephone: Bryant 4796.

Vol. III, No. 10. Whole No. 62 **June 2, 1923** **15c. per copy, $6.00 a year**

Pack Your Radio In Your Old Kit Bag—And Smile, Smile, Smile!

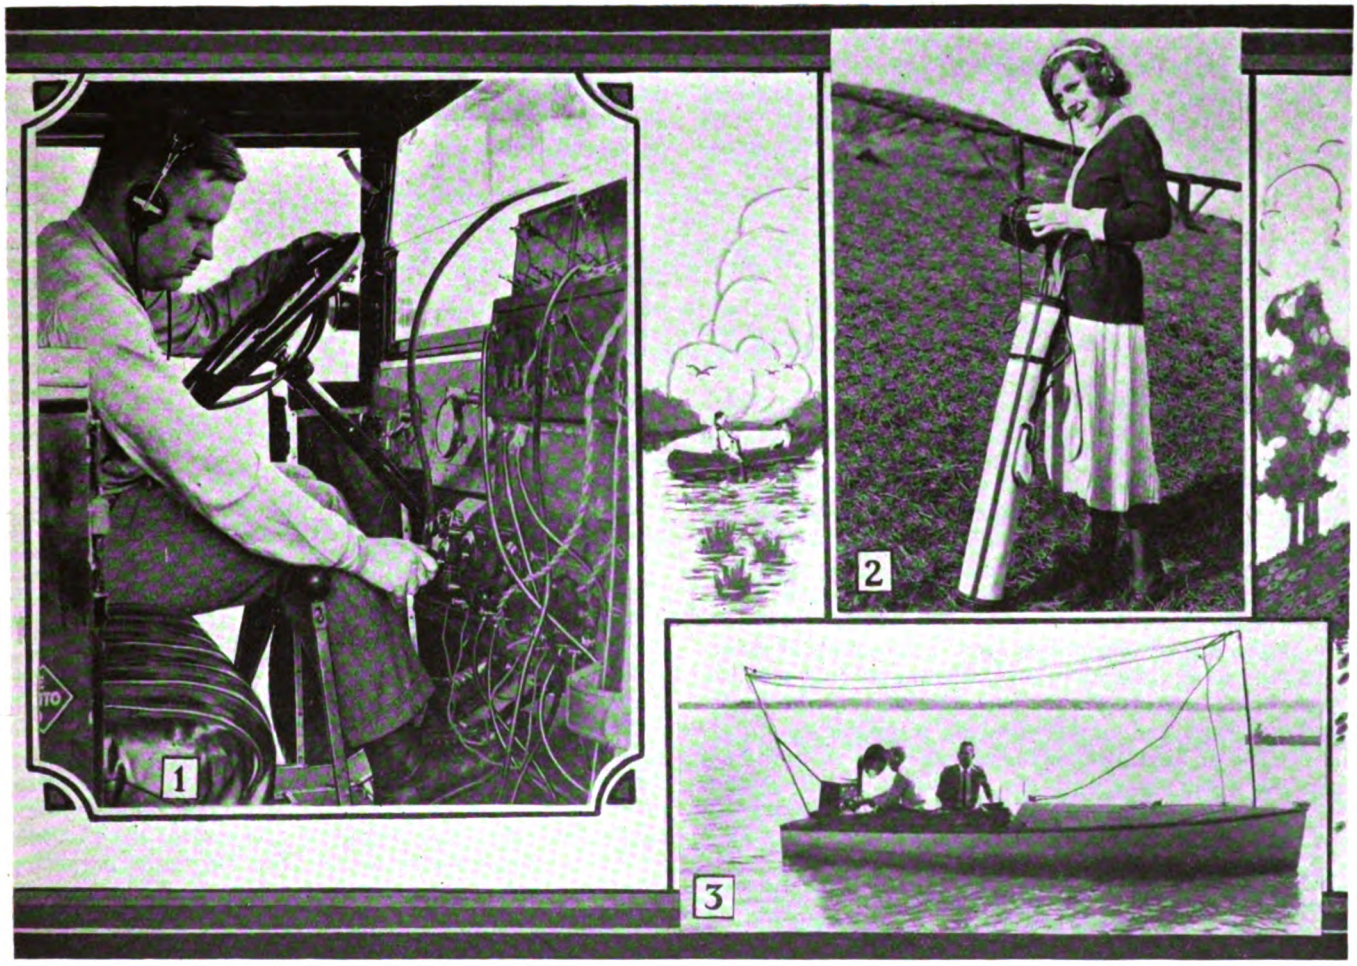
VACATION TIME—the time we all look forward to! The time we shake the dust of the cities from our shoes and prepare to inhale the sweet odor of new-mown hay and put away our troubles and accumulate a good coat of tan.

No matter where you go, farm, woods, mountains, seashore, boating, think of the fun you can have by taking your radio set along with you and not missing your favorite program or concert, and at the same time have the laugh on the folks obliged to stay and swelter in the city.

All you need to do these spring days is to walk through some of the residential sections, or near any private garage, or boat house, and you will see the owners busily equipping their cars and boats with radio sets. A great many are building special sets to put on their boats and take away to camp with them.

Can you imagine anything nicer than sitting around the campfire with the glow of the flames jumping up and casting weird shadows into the dark places, and at the same time listening to Miss Vaughn de Leath and her original radio boys playing "You Gotta See Mamma" or listening to the Symphony in G minor played by Paderewski while sitting comfortably on the porch of your hotel while the crickets and locusts announce the fact that it's going to be a "corking warm day tomorrow"?

Don't just think about it, fan! Look at the pictures on this page and get busy. It won't take you very long to do it, and think of the fun you can have.



(Photos copyrighted by Fotograms, N. Y., and International Newsreel)

No. 1. Who says we can't go radiomotoring? Here is how a rabid enthusiast installed his five-tube set with antenna atop the car so that he wouldn't miss a single thing while going up to the mountains.

No. 2. Did you slice it? Well, just take along that portable tube set, and get a lesson on control from station XZZ and let the next one land plump on the green for a birdie. This is "radio golf" for fair!

No. 3. Atta boy, Petey! Charm those fish with a selection from Faust and then they'll bite without even coaxing. Even at that, isn't it more pleasant to listen to a vocal solo than the "Put-put-put-put" of that dinky motor?

Digitized by Google

Wigwagging With Sharps and Flats

By J. E. Anderson, M. A.

DURING the last three years the writer has been experimenting with a system of signalling which may be called acoustic wigwagging. In certain respects it resembles the system recently announced by General Squier of the Signal Corps of the Army, but instead of using a variation of the intensity of the signal to represent dots and dashes, a variation of the frequency of signal tone has been employed. For instance, the dot is represented by a short duration of a certain audible frequency and the dash with an equal duration of a somewhat lower frequency. Thus a message consists of a sequence of ups and downs of the pitch of the signal tone. At times a third reference frequency lying midway between the other two has been used to facilitate aural reception, in which case the dot is given by a sudden increase in this frequency and the dash by a sudden decrease. Thus signalling becomes a type of wigwagging about the middle reference tone.

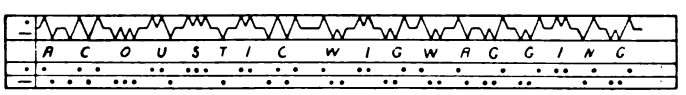
The advantage of this method is especially noticeable in aural reception. Most ears, even if they are not highly musical, are capable of differentiating between two musical tones separated by a fairly small interval, and a coincident variation in the intensity is not a serious matter. The power of the ear to distinguish between two tones is especially great when there is a third frequency with which to compare them. It is easy to tell a sudden drop in a 1,000-cycle frequency to 950, or a sudden rise to 1,050. It is still easier to tell the same absolute variation when the middle reference frequency is a hundred cycles per second. In high speed signalling this auxiliary frequency becomes confusing and it is best not to send it in the body of the message; that is, between dots and dashes and between letters and words. It is still useful, however, at the beginning of signalling after a moment of interruption, and when tuning in on the transmitting station.

When using a variation in the intensity of the signal to represent dots and dashes the ear is unable to differentiate between two intensities unless their ratio differs considerably from unity, and it is impossible to tell whether a sudden change in the intensity is intentional or due to an abrupt change in the attenuation characteristic of the electrical circuit.

This system of acoustic wigwagging is applicable to direct and carrier transmission alike. If instrumental reception is used as well as aural, the frequencies available for use range from the lowest audible to the highest radio for both carrier and direct transmission.

The transmitter for such a system does not differ greatly from the ordinary. The chief difference lies in the oscillator generating the signal frequencies. If the reference frequency is not transmitted the controling key is a single pole double throw switch by means of which one of two condensers may be thrown in parallel with the oscillating coil, the capacities of these being so proportioned as to give the desired frequency interval. It may also be accomplished with a series-parallel switch whereby the two condensers are first either connected in series or in parallel before being connected across the coil. If the reference frequency is transmitted three condensers are used, and the key so arranged that any one of them may be picked up and connected to the oscillating coil. The smallest of these condensers will give the dots, the middle the reference tone, and the largest the dashes.

The circuit used in aural reception is an ordinary receiver and needs no further comment. But when it is desired to render the signals visible, or to record them on a tape, the receiver is somewhat more complicated. The reference frequency is now undesirable and is not used. A tuned circuit is used for each of the signal frequencies. The incoming oscillations are first detected, and then the two signal frequencies are selected by the tuned circuits and separately amplified. The output of the two amplifiers is then used to operate the recording devices. For this purpose a siphon recorder may be used and so arranged that one amplifier pulls the writing point to one side of a median line and the other amplifier in the opposite. A galvanometer in conjunction with a photographic recording device may be also used in the same manner. A better way is to print the message in dots on either side of the median line of a tape. A dot above the line would be a dot in the code and a dot below the line would represent a dash. To operate the printing points local relays are necessary, which are controlled by the incoming signal frequencies. The printing may also be done photographically in which the relays operate two shutters. The two methods of recording a message are illustrated in the accompanying drawing.



Punched tape and recording tape used in "Acoustic Wigwagging." The upper is the received signal and the lower the perforated tape to be sent through the transmitter.

The use of the system described here would increase the possible speed of signalling. The English alphabet as expressed in the International Morse code contains 178 units of time, divided into 38 dashes, 44 dots and 56 spaces. Of these 38 units, or half the units alloted to dashes, are saved. Then assuming that the dots and dashes are equally distributed in a message, there would be an increase in the possible speed of 27 per cent. In the transmission of numerals there would be an increase of 22 per cent., or they could be transmitted in .78 of the original time. A considerably greater increase could be effected by rearranging the alphabet in accordance with the frequency of occurrence of the letters in average English discourse. That is, the two single unit characters should be assigned to the two letters occurring most frequently, the four two unit characters to the four next letters occurring the greatest number of times, and so on.

In ordinary dot and dash transmission, and in the intensity variation system there is only one signal tone. In the system described here there are at least two. An objection has therefore been raised that it takes a wider wave band and is wasteful to the available spectrum. For low frequencies this may be a real objection, but for radio frequencies it is of no consequence. Suppose communication is carried on with a wave length of 400 meters or a frequency of 750 kilocycles. Let the signalling tones be 750 and 1,250 cycles per second. They are separated by an interval sufficiently great to allow complete separation by reasonably selective circuits, and yet when they are modulated with the radio frequency current the total width of the sideband is only one part in 1,500. This would lie well within the resonance characteristic of the radio frequency tuned circuit, and many such channels could be used on the same carrier before it would interfere.

Highly Selective Loose Coupled Circuit Receiver

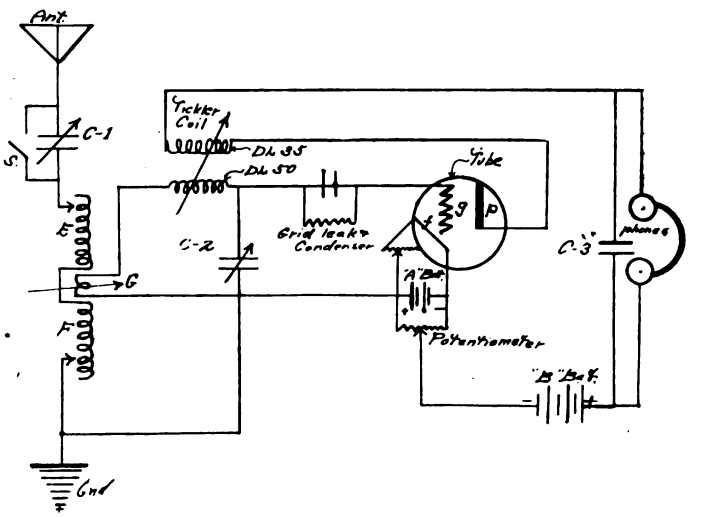
By C. White, Consulting Engineer

THERE has been quite a lot of interest taken of late in coupled circuits of various types. And there has been a lot of misunderstanding and exaggerations as to the benefits of a double and triple circuit receiver. Many have claimed wonderful selectivity with coupled circuits while others have obtained only mediocre results. If two stations are operating on exactly the same wave length and they come in with the same intensity there is no circuit yet developed that will enable you to select one from the other. It is true that we can resort to different tricks to reduce the intensity of one and augment the intensity of the other. One of the most common methods of doing this is to resort to a directional antenna or loop if the two stations happen not to lie in the same direction from the receiver. But it is generally the case that the two are not exactly on the same actual wave length and differentiation or selection can be accomplished by means of a more sensitively tuned or resonant circuit. Then again, if they are on the same wave length, one is most likely louder than the other in audibility to an appreciable extent, thus allowing the coupling to differentiate between the two if the tuner is of the coupled circuit type.

I shall not go into the theory of coupled circuits for Mr. Thompson in previous issues of RADIO WORLD has well covered the subject. But some users of coupled circuits have failed to get the theoretically good results they should because the coupling has been entirely too critical or tight. Then again, the fit between the rotor and stator has been so close that electrostatic coupling has existed when the electromagnetic coupling was zero. Which fact is quite easily explained since the turns on the rotor and stator of the coupler form a condenser whose capacity is not by any means negligible especially when the clearance between the two is very small. There are several methods in vogue to keep this undesirable capacity as low as possible. One method is to make the clearance very large relatively, and another is to place only a few turns on the rotor and have the amount of inductance needed to supply resonance in the secondary circuit added external to the rotor by means of another inductance coil. This fact cannot only be taken advantage of to get the loose coupling, but the tickler coil can be made to feed back into this fixed added inductance. The advantage to be gained by the latter is smooth and even regeneration with more independence of control. With the old, or I should say the more common, system the tickler coil feeds back directly to the secondary rotor and the amount of regeneration was very much dependent upon the coupling and tuning of the primary circuit. It is a great help to be able to set your regeneration to a maximum and then go ahead and finish the fine points in the final tuning in, without the disagreeable annoyance of the tube jumping into sudden oscillation or spilling over.

In the accompanying illustration is shown the essential connections of the circuit. The unit E, F, G is the main tuning unit. The coils E and F form the stator of the element. The coil E consists of 25 turns tapped every five turns while the coil F consists of 25 turns the last 10 of which are tapped every two turns to allow finer adjustment of inductance. The whole stator is wound on a four inch bakelite or formica tube with No. 18 D.C.C. magnet wire. The coils should be wound with a piece of string between each turn to assure a spacing between any two adjacent wires of each coil. The spacing between the coils E and F should be ample enough to allow room for the rotor shaft to pass through with sufficient clearance on each side. The rotor (G) should be wound on a good insulated form and have only five turns of No. 18 D.C.C. wire, spaced in a similar manner as the stator turns. After the coils are wound with the string between each turn they can be coated with coil cement and upon drying the string can be removed. The reason for using No. 18 wire is to keep the resistance of the tuning circuit as low as possible and the reason for spacing the turns is to keep the amount of distributed capacity of the coils at a minimum. Of course, a smaller size of wire could have been employed for the rotor coil G, but why go to the trouble and expense of purchasing another size wire? A honeycomb coil (DL50) is used to complete the inductance quota for the secondary while a honeycomb (DL35) is inductively coupled to the former to obtain regeneration. These two coils should be provided with satisfactory mounts in order gradually to adjust the coupling. If a DL35 coil is not easily procurable a DL50 can be substituted.

The condenser C-1 of the primary tuning circuit is an



Do you want selectivity? Then construct this set and you will get it.

ordinary 11 plate air variable shunted with a short-circuit switch to allow the primary to operate untuned if such is preferable. The condenser C-2 is of similar type and size and is used to tune the secondary circuit. Some prefer to operate with the secondary untuned and the primary tuned, but if the condenser is placed in the circuit the amateur will have his choice and can easily weigh the merits of each method. The grid leak resistance and the grid leak condenser will depend solely upon the kind of vacuum tube employed as a detector. Generally two megohms and .00025 mfd. capacity will suffice for most cases. The condenser C-3 is a mica by-pass condenser of .001 mfd. A potentiometer is provided in order to furnish a further fine adjustment of regeneration.

Those fans who have tried out the regular single circuit regenerative outfit and now wish to change their circuit and experiment will do well to investigate the loose coupled type of receiver. In construction care should be taken to see that the DL50 coil is mounted at right angles and some little distance away from the stator E and F so as to prevent electromagnetic coupling where it is not wanted.

Some Good Radio Kinks for Yachtsmen

By Arthur S. Gordon

SOME years ago yacht owners awoke to the fact that it was quite possible to take a victrola to sea without running any risk of pounding the records to small bits on the bounding billows. As a result, the laziness of long cruises was somewhat relieved by a snatch or two of music. At the present day, cabin cruisers and houseboats have talking machines built in the cabin woodwork as a matter of course. Now along comes radio with its intense fascination, and progressive yachtsmen are considerably upset. While they haven't as yet ordered radio sets made a part of their boat, like the rudder or the anchor, they are

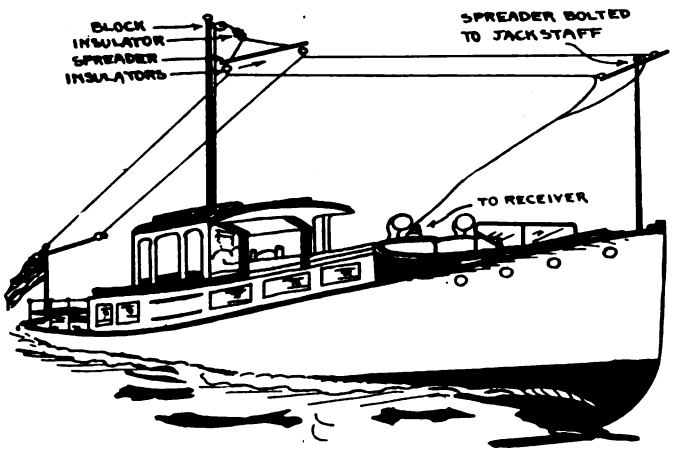

Fig. 1. The antenna installation on a typical cabin cruiser. This not only serves as an antenna, but gives the cruiser a sub-chaser aspect.

wondering why it can't be done—and the answer is, "It can!"

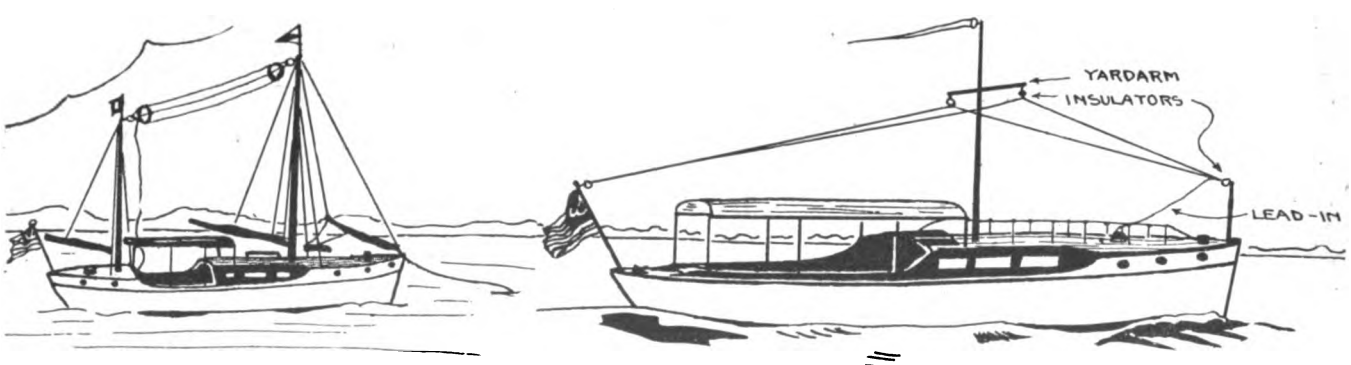
Of course, it isn't practical to load a three, four or five tube set, with batteries and such complete, within the gunwales of a boat that is scarcely large enough to carry an extra hand when the captain-crew-and-cook is on board. Neither is it the height of good sense to install a radio on a speed shingle like "Miss Margaret" or "Miss Broadway." Racing sloops and yawls are also barred, because when they are under way in a stiff breeze, their proud owners just haven't time to do anything else but handle them. Even if they did manage to snatch a moment at a radio set, the angle of their craft would prevent them from enjoying whatever they might hear. With all these vessels out of the contest, therefore, it remains to be said that on the contrary, there are types of boats that just cry out loud for a radio installation. What excuse has the owner of a roomy, comfortable houseboat, for example, or a moderately spacious cabin cruiser, for not having at least a radio receiver on board?

Aside from everything else, the important question with yachtsmen has been, "Is it possible on a small boat, say from 30 to 40 feet over all, to erect an antenna that will function satisfactorily with a moderately priced and easily operated receiver?" The answer is an emphatic "Yes!" Take houseboats, or cabin cruisers, for example. The problem of an antenna on craft of their nature is easily solved. There is always a tall mast afore or abaft the wheelhouse, and this may be used as the high point of the installation. From the masthead a flat top or cage aerial may extend both forward and aft to the jack and flagstaff, respectively, with the lead-in coming from the end nearest to the location of the apparatus. Fig. 1 shows the typical aerial installation on a popular make of cabin cruiser.

Another type of marine antenna, and one that is perhaps seen the most, takes advantage of the crosstree yardarm on the mast. An insulator is hung from each end, and the aerial wires are suspended from them, coming to a point at both the bow and the stern. This is illustrated in Fig. 2. Still another type is that found on auxiliary cruisers with two or more masts. This type resembles more closely than the others the aerial construction on cargo and passenger vessels of the Merchant Marine, and may be either of flat top or cage design. In this case, the lead-in should come down the mast, running either inside the mast hoops or otherwise well clear of any tackle that concerns only the sails of the vessel. This is illustrated in Fig. 3.

The greatest care should be taken in insulating the shipboard aerial. No part of it should touch the vessel. No part of it should be left free to swing or sag against any of the standing or running rigging. This rule of perfect insulation is inflexible where boat aerials are concerned, for it must be remembered that when the yacht is wet from either heavy seas or rain, it is practically grounded.

Otherwise an instrument ground is provided by running a wire from the set to a beam or plate in the vessel, providing that this beam or plate is of metal and connects with the hull, also of metal. If all these should be of wood, provide your own plate by screwing an unpainted strip of copper sheeting on either side of the outer hull just above the keel. This strip should be about one foot wide and four or five feet long. Copper is recommended because of its non-corrosive properties. Some vessels are copper-sheathed just be-



Figs. 2 and 3. Two other methods of installing antenna on different types of boats. The yawl is very difficult because of the limited space; therefore, a cage type antenna is suggested.

(*Continued on next page*)

Digitized by Google

(*Continued from preceding page*)

low the waterline. This sheathing is an ideal radio ground. Others have metal bilge keels and these, too, are suitable. The idea is either to provide a metallic area exposed to the water, or a counterpoise in the form of the paint-insulated metal frame of the vessel itself. Should the metal frame not be insulated from the water, all the better.

The antenna-ground installation is not complete on a small boat without a short circuit switch or an arrester gap shunted across the aerial-ground terminals of the set. If a switch is used, the one employed should be of the single pole, single throw type, and should be connected as shown in Fig. 4. In this diagram, the switch may be replaced by an arrester gap, the only difference being that the gap is automatic, while the switch needs faithful attention, to be at all effective when the time comes for it to function. It will be noticed that the same ground is used for both the gap and the receiver. This is contrary to house practice, but on a boat there are neither legal nor technical objections to such an arrangement.

Although it is not "such a much," the masthead aerial is surely the equal of attic antennae, molding aerials, and the electric lighting circuit. If amateurs can do creditable D X work with these indoor makeshifts, using only a two or three tube straight audio-frequency hook-up, what is to prevent the yachtsman from doing the same with his miniature aerial? Too many people assume that because a fellow has a boat, he is a millionaire. They also assume that he is of that peculiar breed of human beings who want nothing but the very latest, regardless of the good points possessed by standard and well-tried outfits. Acting under these generous delusions, they recommend to the yacht owner a high-voltage, multi-tube, myriad knob affair that even a radio engineer couldn't handle on dry land, let alone a comparative novice on the deep sea. This, of course, is all wrong. Four or five tubes are not necessary. On the contrary, a single tube receiver stationed in New York harbor and vicinity should bring in the big New York and Newark stations without any trouble whatever.

For off-coast cruisers, however, at least a three tube set is recommended. The conventional regenerative circuit employing one tube as a detector and the other two as amplifiers is quite all right, but if the extra transformers do not complicate matters, it is much more efficient to employ the recently popularized reflex circuit, in which each tube is made to do double duty as both a radio-frequency and audio-frequency amplifier. Should the reflex circuit be used, it is advisable to use a tube instead of a crystal for a detector—that is, unless the prospective operator has come across a synthetic crystal that needs no adjusting whatever. A suitable circuit of this nature is the Grimes inverse duplex, given in Fig. 5. In this circuit there are three tubes, two of which are used in reflex and the third employed solely as a detector. It works surprisingly well with a small shipboard aerial and is therefore suggested as the general type of hook-up which is supremely suited for the yachtsman.

If an owner's fancy runs to loop antennae, and there is room aboard his vessel to swing one, let him select a hook-up in which the loop is not an integral part of the primary tuning system. In other words, a circuit which employs the loop merely as a collector of energy and not as a strongly directional device to tune out one station and bring in another by a mere touch of the loop. Otherwise, he is going to be annoyed by the manner in which the loop turns with the ship's head, and by the irritating regularity with which good concerts suddenly disappear from whence they came. This annoyance is not only present while the yacht is under way, but also while it is swinging at an anchorage.

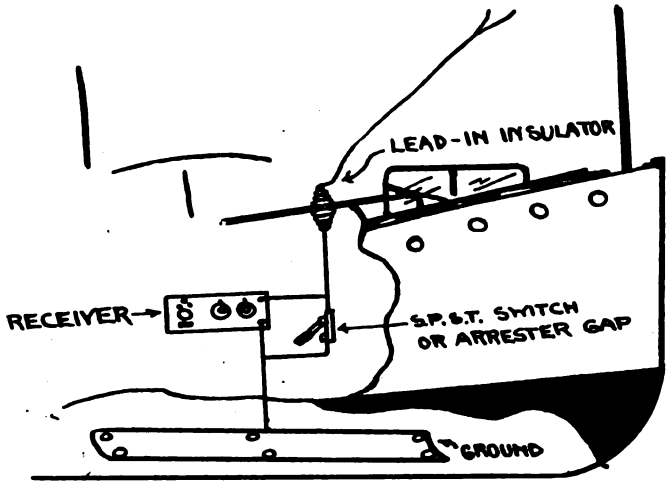


Fig. 4. A safety switch or gap should be provided. The ground can easily be effected by use of a metallic plate, and both instruments and gap are grounded to it.

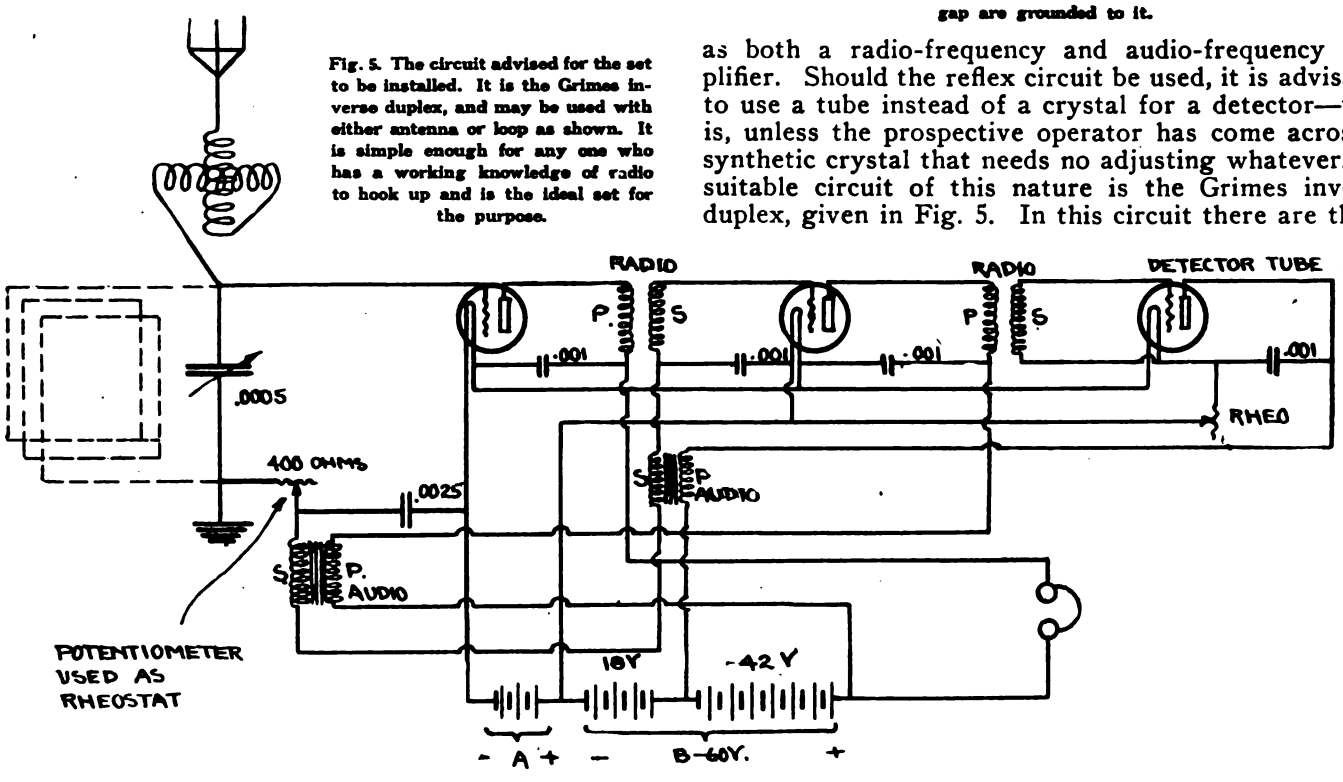

Fig. 5. The circuit advised for the set to be installed. It is the Grimes inverse duplex, and may be used with either antenna or loop as shown. It is simple enough for any one who has a working knowledge of radio to hook up and is the ideal set for the purpose.

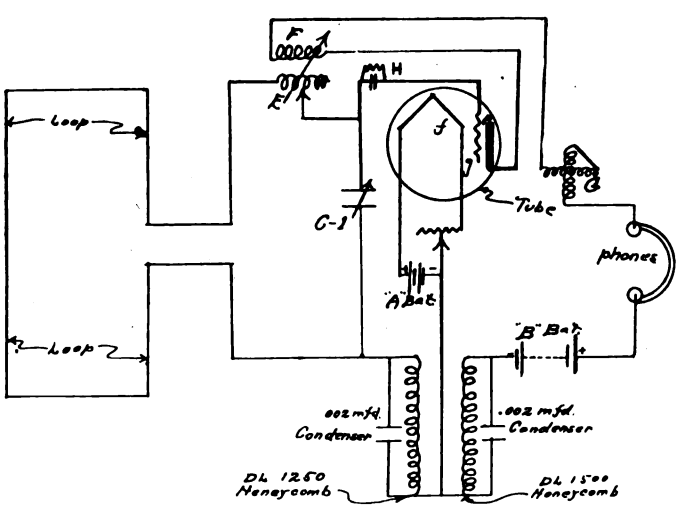
A Portable Loop Aerial Receiver

By C. White, Consulting Engineer

THERE is little doubt in the minds of many radio experts and amateurs that the coming type of antenna will be the loop aerial. The outdoor aerial is not only an excellent collector of atmospherics in the warm weather season, but is equally as proficient in gathering disturbance from Friend Radio Neighbor who does not operate his regenerative receiver properly and generally supplies you with a varied assortment of howls and whistles. Then again, the outside antenna adds little to the selectivity of your outfit and, in fact, in some cases where it is improperly constructed it actually subtracts from the sharpness of tuning. Aside from all these disadvantages it has the added inconvenience of being rather hard to install in most apartment house cities, and does not lend itself to portable radio equipment and field use in summer camps unless exceptional conditions are available. It is, however, many times more efficient than the loop from the standpoint as a collector of radio-frequency signals, but after careful considerations of all its merits and demerits the average fan will agree that it is much



Circuit diagram for a compact loop receiver that can be easily constructed to fit in a small sized suit case or portable cabinet, using the popular dry cell tube.

better to add a tube or change a circuit in order to get rid of it in favor of the loop. If you once get used to the loop with its sharp tuning and quiet operating possibilities you will not for one moment return to the old type of aerial.

It is quite true that a loop aerial can be used on your present regenerative receiver with little or no changes in the circuit you are at present using, but with such an arrangement you cannot hope to pull in the distance that an outside antenna affords. To overcome the low collecting power of the loop we must resort to either radio-frequency, amplification or regeneration on a "super" or "ultra" scale. With the former it will be quite necessary to resort to the use of additional tubes, but by means of the latter we can get remarkable results without the employment of any more tubes than we would have on an ordinary receiver. The circuit that I shall endeavor briefly to outline is nothing more than a modified form of the old "ultra" regenerative circuit. By means of the few modifications it is easier to control and much more flexible to operate than most of the older types which use one tube. Regeneration to an extreme point is easily obtainable with a loop because of its quiet operation and the fact that the fellow next door can not cause your tube to slip or jump into oscillation.

The schematic connections are clearly shown in the accompanying diagram. The loop is about 30 inches long per side and is square in shape. It should be wound with braided copper ribbon or specially stranded radio-frequency wire so as to cut down the high or radio-frequency resistance in order to increase signal strength and selectivity. The coil should have eight turns in all and the corners of the loop frame which supports the wire of the loop should be made of bakelite so as to prevent or minimize high frequency leakage which would be very large if the wires rested on a wooden support such as the body of the frame. The lead or terminal wires running from the loop to the set proper should be kept as far apart as possible and should be well insulated from each other. Every possible means to conserve the small amount of signal energy collected must be exerted. The cabinet holding the working parts ought to be fully shielded with copper foil and the movable plates of the condenser C-1 are to be connected to the filament side of the tuning circuit, which is grounded to the copper foil shielding. In some cases it is advisable to ground to earth connection the copper foil and the negative side of the "A" battery, but better results are often obtained when the set is operated without ground connection to earth. You can easily try out both methods and determine which case better fulfills your requirements.

The constants for the circuit are as follows: C-1 is an 11 plate air variable with some good reliable sort of vernier adjustment or attachment; E is the stator coil of an ordinary variocoupler, while F is the rotor of the coupler; G is a standard type of variometer; and H is a good grid condenser and a reliable grid leak resistance. The two DL honeycomb coils should be furnished with a substantial mounting in order that the coupling between the two may easily be varied. It is not necessary to go to the expense of purchasing an elaborate variocoupler because only a few turns of the stator of this coupler will be in actual use on short wave reception, owing to the fact that the inductance of the loop alone will almost be sufficient to accomplish the necessary tuning, and the plate variometer G will supply most of the regeneration, while the rotor F will perform a sort of vernier regeneration control. The "super" part is accomplished by means of the coupling between the two honeycomb coils, which is kept very loose (that is with the coils far apart) until the receiver has been completely tuned as a regenerative receiver; then it comes into play. By its use the grid of the tube is biased positive and negative at a high frequency rate. The very fact that the biasing is done with alternating current makes it possible to hold the tube on an extremely critical and sensitive point since the negative impulse tends to push it over and the positive pulls it back from oscillation before it gets a chance to respond to the negative pushing impulse.

Let me repeat that this set can be made extremely compact and readily lends itself to camp and field use. It is almost an ideal set to use for summer work since it can be carried complete with very little trouble. For stations not over 25 or 30 miles distant the reception comes in with the volume of a good regenerative receiver using two stages of audio-frequency amplification and an outside aerial.

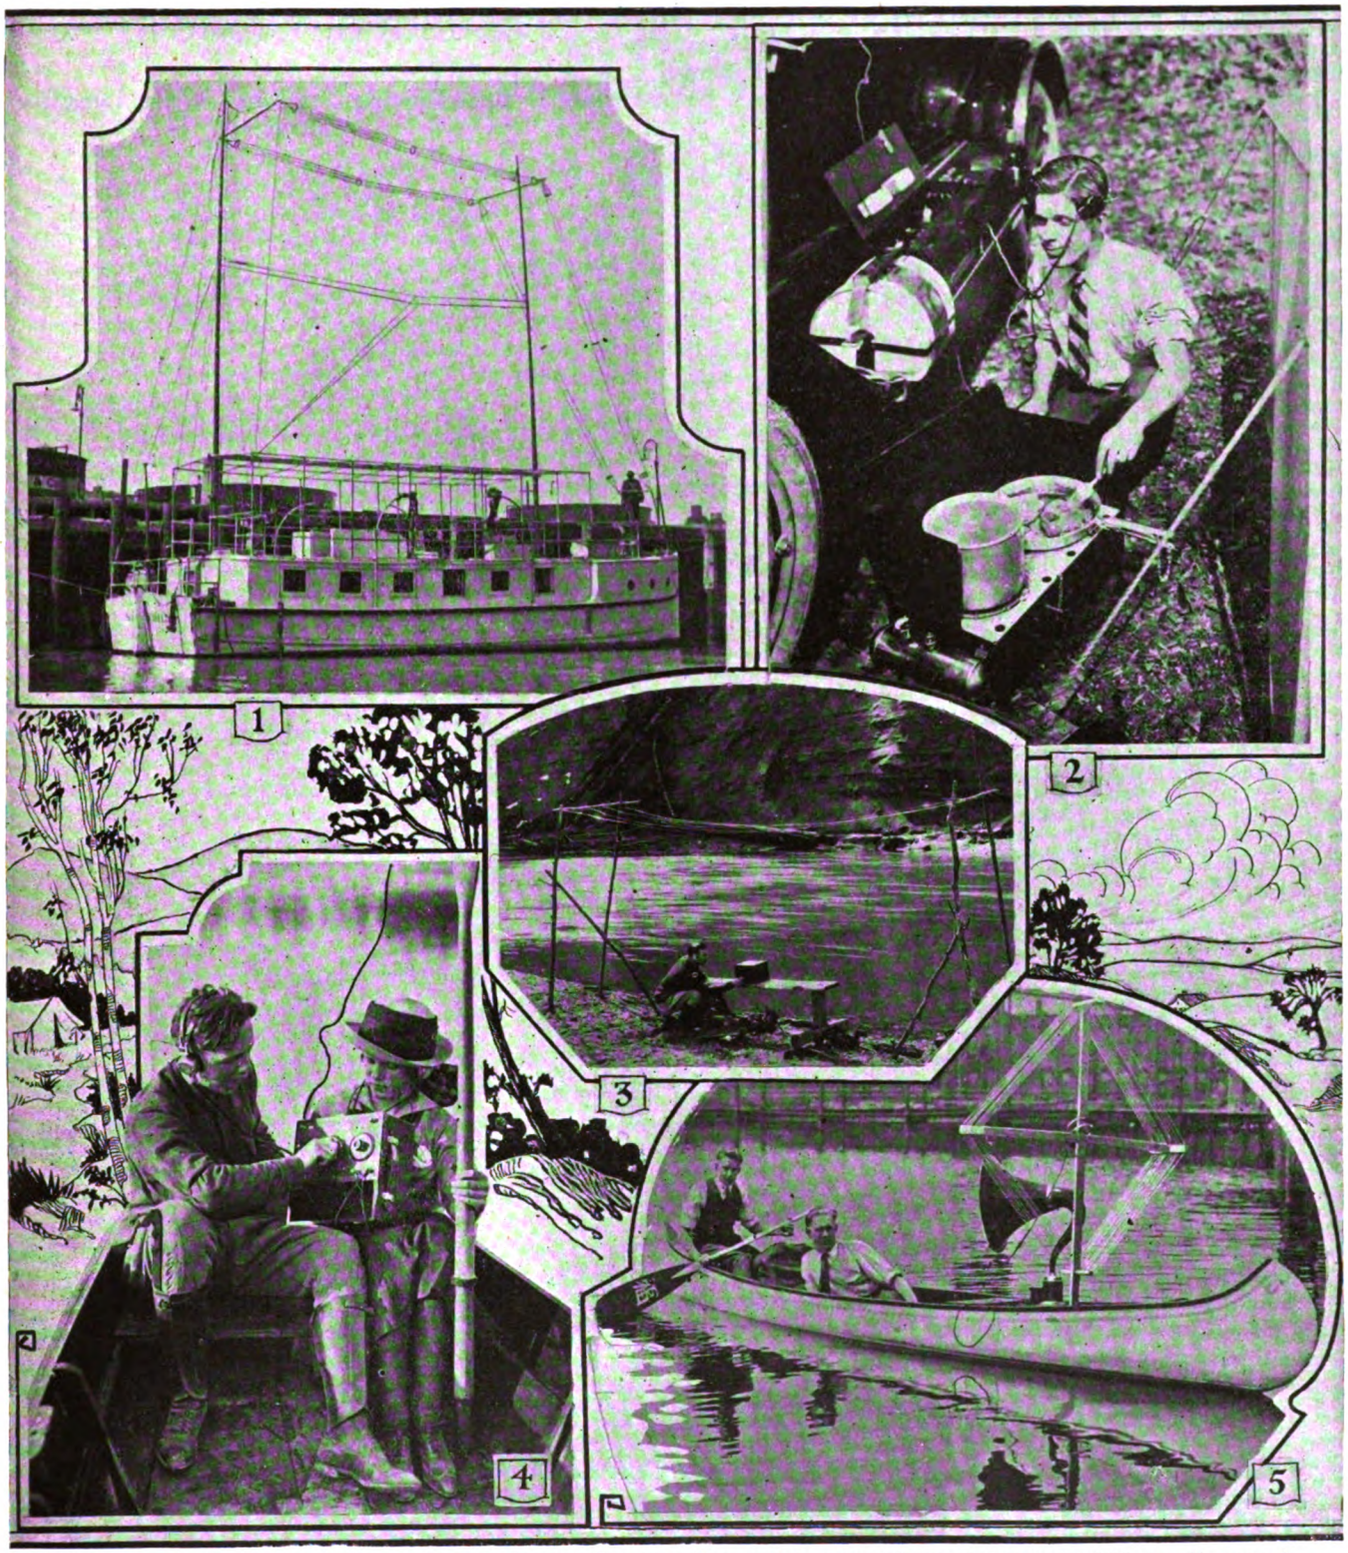
The Infinite Variety of Radio for Summer Pleasure Is Told In These Pictures



(Photographs copyrighted by Underwood and Underwood, Kadel and Herbert, International Newsreel, International Photos, Photonews.)

No. 1. How one staid vacationist is going to be entertained during his trip on a houseboat is plainly visible. He didn't wait for any suggestions, but just went ahead and "did it."

No. 2. What could be finer than some nice bacon and eggs and "You Gotta See Mamma Every Night" over the radio while camping via auto this summer? Beats cabaretting!

No. 3. This is how they do it out in Washington when they go camping along the Green River. Kinda primeval antenna, but it gets KHJ and all the rest, so why worry?

No. 4. Here's a new one, fellas! Use one of your oars to support the loop and bring 'em in fine.

No. 5. It used to be "Give Me the Moonlight, etc." Now it's changed to "Give me my canoe, give me my set, and let the sigs roar in."

"Before This Wonder Distance Shrinks"

By Grace Isabel Colbron

Written for the opening of Broadcast Central, the new station at Aeolian Hall, New York

FLINGING free from the guardian wires, into the blue alone,
The human voices goes soaring forth, the simple spoken tone
Bridging the breadth of the sea's expanse, the mountains' cloud-capt height,
Over the fertile prairies broad, the forests' fragrant night.
Calling across from land to land the greetings of friendship go,
With the intimate touch of the spoken word, its warm and human glow.
Before this Wonder the distance shrinks and a listening world draws close,
Its petty envies and hates forgot as the sense of Brotherhood grows.
Before this Wonder the past gleams pale, but the future with promise bright,
For the spoken word on the Radio heralds a New Dawn's light.

How to Buck the Bugaboo of Summer Static

A Properly Installed Aerial Offers Better Protection Than a Lightning Rod

By Kenneth Malcolm, A. I. R. E.

AS the summer months approach, the embryo radio fan will be introduced to a phenomenon which he may consider entirely unnecessary and unwelcome. It makes itself known as a continuous or interrupted series of cracklings and snappings and is known as "strays," "atmospherics," or more commonly, "static."

Hitherto, static has always been a bugbear to the amateur and commercial operator alike. Its nature was only partly known, and efficient methods for eliminating it or reducing it were not available. Every summer, however, finds new progress and today, with modern developments, for most work it can be eliminated. The broadcast listener need have very little trouble with it, if he will only observe a few precautions.

First, let us look at its nature; and by finding its cause we will be better able to prescribe a remedy.

Dry air is a very good insulator. Clouds are partial conductors. When clouds are blown by the winds over charged earth, or even through supposedly uncharged air, they acquire a charge of electricity of their own, due to friction and induction. If the air is damp and humid this charge tends to leak off, with the result that finally the potential is entirely gone and the earth-cloud system is perfectly balanced.

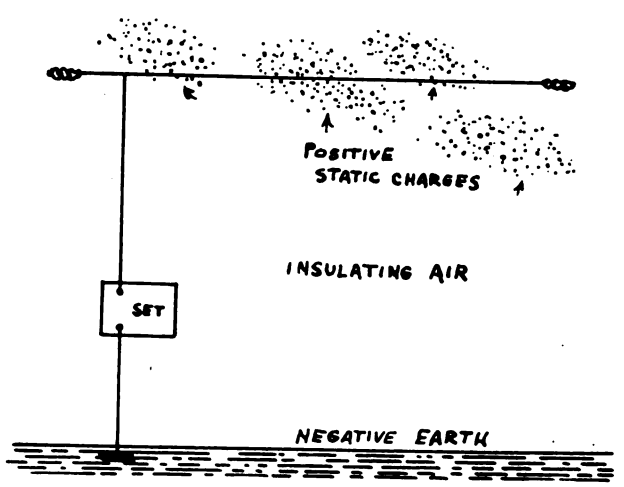
But when the air is dry, the cloud and its surrounding atmosphere retain the charge and possibly increase it. It can't leak off, because there is an almost impenetrable insulator between it and the oppositely charged earth. However, when a cloud comes near to the earth or near to an oppositely charged cloud, and the charge is great enough, the air will be completely disrupted. Such a discharge we see as lightning, and the following crash we call thunder. Lightning generally occurs after the rain has started to fall, for then the resistance of the air is lowest.

Miniature lightning has been produced artificially by Tesla and Steinmetz in their famed high-potential experimental laboratories, the difference being only in the potential. Natural lightning ranges up in the millions and hundreds of millions of volts.

While charges of lightning potential accumulate only in certain widely separated sections, lesser charges are present most of the time. These lesser charges are generally the cause of static. Your aerial is suspended high in the air, and one end, through your set, is grounded. The charges floating in the air find in your aerial an easy means to reach the earth, with the result that you hear them discharging through your set. Sometimes distant lightning discharges propagate waves somewhat similar to the waves sent from a radio station, and this is another cause of the disagreeable noises.

Is an aerial strung over your house a lightning menace? Emphatically not! A properly installed aerial, with a lightning switch or an approved lightning arrester, will offer as much, if not greater, protection as the old-fashioned lightning rod. Communities equipped with many high-strung antennae ought to be perfectly free from any lightning danger. The notion that a little aerial wire would *attract* lightning is absolutely absurd. Metal chimneys, tin roofs, metal leaders, and steel clothes lines could be condemned with greater justification.

Now let us consider the methods that may be used to reduce static so that reception may be enjoyed as much in the summer time as in the winter—let's not pack our sets in camphor balls this season. The first suggestion is that you reduce the height and length of



Diagrammatic representation of atmospheric conditions producing static effects.

your aerial during the summer months—for the nearer the earth, the less static; and the shorter the aerial the less foot-hold it can get. Do this within reasonable limits, however; don't make the aerial so short and so low that reception is impossible with the particular set you have. An aerial about 80 feet long and 20 feet high might be a good size. If this cuts your wave length range down too much, a small loading coil can be added to compensate. If the roof of your house is not of metal, you can string the aerial in your attic, or in the space usually provided between the roof and the ceiling of the top story, with a considerable static reduction.

For those who live in the open country, the ground antenna might be a fit solution to the static problem. Much data has been published on this type of aerial and no more than mention need be given here. It consists, essentially, of heavily insulated wires buried in long shallow troughs in the earth.

The loop is perhaps the most ideal form of static eliminator. The main disadvantage is that with such an aerial reception over any but very short distances must usually be done with the aid of radio-frequency

Elementary Instruction for the New Army of Radio Beginners

Constantly Used Terms Explained in Plain Language for the New Radio Enthusiast

By Lynn Brooks

VARIABLE CONDENSER: It has been found in radio telegraphy and telephony that capacity is a very necessary element in the tuning of a set. Therefore in order to increase the range of such capacitance and increase its usefulness, it has been made variable over a large scale. The variable condensers most commonly used consist of a number of fixed plates, semicircular in shape, and held in place a certain definite space apart, by means of long bolts and washers. Between the spaces of these plates are another set of semicircular plates which are slightly smaller in size, so as to allow them to rotate freely inside the first without touching the washer. The number of plates in such condensers varies from three to as high as 60, depending upon the use to which they are to be put. Their method of variation is to rotate the inner plates. When the plates of the rotor are all intermeshed with the plates of the stationary set, the capacity is at a maximum. As the plates are rotated and more of the surface of the rotating plates is withdrawn the lower the capacity becomes, until when the plates are exactly opposite the capacity is at its minimum. Another and quite common form of variable condenser is that using the surface of two large plates. One of them is stationary and the second can increase or decrease the distance between the flat surface of both by means of a very fine machine screw. In order to prevent short circuiting, it is generally the custom to insulate one of the plates by means of a very thin sheet of mica, or coating one of the plates with some other thin insulating compound. As the distance between these two plates is varied the capacity is accordingly varied. The closer the plates the higher the capacity, and the maximum is reached when there is no air space between the two, and only the thin insulator is separating them.

FIXED CONDENSER: In many places in a circuit it is necessary to use capacity, but because of the fact that the capacity does not need to vary a fixed condenser is used. A fixed condenser is one whose construction does not permit of variance. It is generally made of a number of metallic plates separated by a suitable dielectric. These plates are of fixed size and arranged in a pile, one on top of the other, and with a suitable binder to hold them together. The determining factors in such a condenser are the number of plates, the thickness of the dielectric, the total area of plate surface on one side and the dielectric constant for the particular insulating media used.

GRID LEAK: As we have before stated, the grid in a vacuum tube acts as a gate to let the negative electrons pass, or hold them back, depending upon the condition of the grid. As the polarity of the grid has to change, some method of allowing the negative electrons to pass off around the condenser must be had. To do this what is known as a grid leak is provided. This is a very high resistance (non-inductive) over which the electrons can pass when sufficient have accumulated and done their work on the grid. Numerous methods of making a grid leak are found. The commonest is to soak a piece of paper or cardboard in India ink, letting it dry and then placing it in the circuit. Other methods consist of making a pencil mark on paper and using that, or using graphite in the form of a paste in a tube. In most of the tubes used at the present time, the conditions call for a variable grid leak for the proper manipulation of the tube. In the pencil mark type this is accomplished by erasing the lines or making them heavier. In the India ink type it is accomplished by either lengthening or shortening the paper, or using a slider for one end of the contact.

(*Concluded from preceding page*)

amplification. However, with some of the new super-regenerative and reflex circuits this trouble may to a large extent be done away with. Within 15 or 20 miles a loop may be used with even a plain single tube regenerative set.

The simplest loop set can be made by connecting the loop terminals at the point where the terminals of the secondary of a variocoupler would be placed in the regular three-circuit regenerative set. A vernier variable condenser is used for the tuning. Such an arrangement offers great selectivity as well as freedom from static, and will work well over moderate distances.

The single tube super-regenerator is quite good for loop reception and, on account of its greater ease of control, the single tube reflex circuit is a trifle better. These two types are dandy for portable sets, in connection with dry cell tubes.

Of course, the regular radio-frequency amplification sets may be used with positive results. They are both very dependable and selective. For those who can afford them they are the best buy. Use one, two, three, or as many stages as you need to cover your distance. The two and three tube "super" and reflex sets are not to be forgotten.

If you use a regular crystal or vacuum tube circuit, with a regular aerial, you may reduce static considerably by avoiding series condensers. These tend to store the energy and discharge at the most inopportune times. Reducing the coupling between the coils of your variocoupler or variable condenser may help considerably. Static charges are not as willing as radio waves to jump between coils that are magnetically coupled.

A number of balanced tuners and balanced aerials have been devised from time to time, and with more or less success, but they are of interest to the commercial operator and engineer more than to the broadcast listener, because of their complexity and comparative cost.

Static is more than a nuisance; it is a fiend that costs the radio companies millions of dollars annually.

Why is it that an amateur can span the Atlantic with 100 watts, whereas the big trans-Atlantic commercial stations fling out an energy 2,000 times this amount? And an amateur's aerial can be a measly 100 feet, while the commercial giant must have an aerial of five miles? The answer is simply "static!" When the amateurs and the broadcasting stations get across, the air is most free from this pest. But commercial stations must carry on continuous service, with the result that they must bang and batter their way through the static barrier—and at an expense of hundreds of times the energy that would otherwise be required. A satisfactory solution to this problem means a fortune to the inventor.

RADIOGRAMS

WORLD NEWS HAPPENINGS BRIEFLY PHRASED FOR BUSY READERS

Sir Samuel Hoare, Air Minister of Great Britain, was informed of the appointment of Stanley Baldwin as Premier by wireless telephone as he was on his way by airplane from London to Cologne.

* * *

The Minneapolis Journal not long ago announced a need of $5,000 for a radio fund for the unfortunate patients of the Glenlake Tuberculosis Sanitarium. In three days over 1,000 persons voluntarily sent $7,741 to the Journal.

* * *

A. Frederick Collins, author of a number of scientific works and several books on wireless telegraphy, has been elected a Fellow of the Royal Astronomical Society and a member of the Radio Society of Great Britain.

* * *

Dr. Samuel Wesley Stratton, formerly Director of the Bureau of Standards at Washington, D. C., will be inaugurated as President of the Massachusetts Institute of Technology in Symphony Hall, Boston, on the morning of June 11.

* * *

Engineering extension courses by radio may be established at Pennsylvania State College. The engineering extension department, Dean Sackett is quoted as saying, already reaches 9,000 industrial employees each year, with class and home study courses.

* * *

Georges De Launay, a well-known pianist and conductor of the Paris Orchestra, recently made a formal protest against the installation of a wireless telephone transmitter in the concert hall where he was to play and refused to begin the concert if it was used.

* * *

Guynemer Post of the American Legion, of New York, composed of veterans of the air and radio services, claims to have been the first post to broadcast its meeting announcements by radio. This was done in 1919 before there were any commercial broadcasting stations.

* * *

The naval radio station established at Cape May, N. J., during the war has been dismantled and the equipment will be installed at Lewes, Del. The naval radio compass station at Cape May will remain there, but hereafter all naval vessels will flash their radios to the new station.

Radio signals are believed by some scientists to travel forever in the infinite. If this is true, the signals made in Marconi's original experiments are still on their way following those generated earlier by Tesla and others.

* * *

Wireless broadcasting of religious services should be confined to week-days so that Sunday may be left for public worship, according to an address delivered at Minneapolis, Minn., by the Rev. Phillips E. Osgood, rector of St. Mark's Protestant Episcopal Church.

* * *

Harris J. Ryan, professor of electrical engineering at Stanford University, California, was elected president of the American Institute of Electrical Engineers at the recent annual business meeting held in New York City. The total membership of the institute on April 30 was 15,298.

* * *

Kurt Hildesheimer informs RADIO WORLD that a few weeks ago the first German amateur radio club was organized in Berlin. It will devote its energies to popularizing radio. The address is Deutsche Radio Club, Berlin C2, An der Stechbahn 1, Germany. Mr. Hildeheimer writes: "Let us hope that the international science of broadcasting will help overcome some of the artificial barriers between the world's nations."

* * *

Edward J. Nally, managing director of International Relations for the Radio Corporation of America, returned last week from a trip to South America and reported that the construction of the huge wireless sending station a few miles south of Buenos Aires will place South America in touch with the entire world. He said that the new station would be completed in August and other stations would then be constructed at Rio de Janeiro and Pernambuco.

* * *

The Eiffel Tower wireless transmitting station in Paris was put out of commission by lightning one day recently, when a bolt struck the antennae, 1,000 feet above ground, and the entire apparatus crashed to earth. While rush repairs were being made the station was silent and thousands of radio fans missed their daily broadcasting program and evening concert as well as the time signal which is given every noon. Another wireless station near Tours substituted part of the time for the Eiffel Tower station.

Schedule of Standard Wave Length Tests from Station 1XM

STATION 1XM, at the Massachusetts Institute of Technology, Cambridge, Mass., will broadcast standard wave length test signals at the hours and dates enumerated in the schedule below. The time used is Eastern daylight saving time. Eastern amateurs and station operators are thus afforded an unusual opportunity to calibrate their wave meters and sets.

The schedule follows:

Time	Wave Lengths in Meters	
P. M.	June 4	June 11
7 00	220	380
7 05	210	360
7 10	200	340
7 15	190	320
7 20	180	300
7 25	170	280
7 30	160	260
7 35	150	240
7 40	140	220
7 45	130	...
7 50	120	...
7 55	110	...
10 00	...	110
10 05	...	100
10 10	...	90
10 15	...	80
10 20	...	70
10 25	...	60
10 30	...	50
10 35	...	40

During the first minute of each five the wave will be announced in code. During the next two minutes the wave will be indicated by dashes corresponding to the figures; that is, 320 meters will be indicated by three dashes, two dashes and one long dash; 380 will be indicated by three dashes, eight dashes, and one long dash, and so on down the scale.

Directions for Building a Portable Loop for Summer Portage

By Arthur G. Shirt

GOING camping this summer? Canoeing? Or cruising up the coast to Maine or down it to Miami? Going to take a radio along? If so, you'll need a portable antenna that will fold up like an army cot, that will fit under your arm, across your back, in your canoe and that, when unfolded, will bring in the broadcasters from seven states, with the minimum of interference and atmospherics. You'll need something that, notwithstanding its collapsible nature, is strong and sturdy, so that it will stand the rough usage of the camp and country. A loop, for instance, designed especially for vacation use by an expert in loop construction—one that you can make yourself, that doesn't cost a fortune to build, and so on.

Making a loop is not as easy as it looks. Amateurs who have tried it know the unstable botch that results when certain vulnerable spots in frame construction have been neglected. The particular difficulties in making a portable loop are first of all, to make it a practical asset to the receiving set and not an irritable annoyance; then to make it so that its component parts fit as well when spread out for reception as they do when folded for portage. If the plans given herewith are followed reasonably close, the above-mentioned difficulties will be smoothed out with no trouble at all.

Procure a strip of light wood ¾-inch thick, 1½

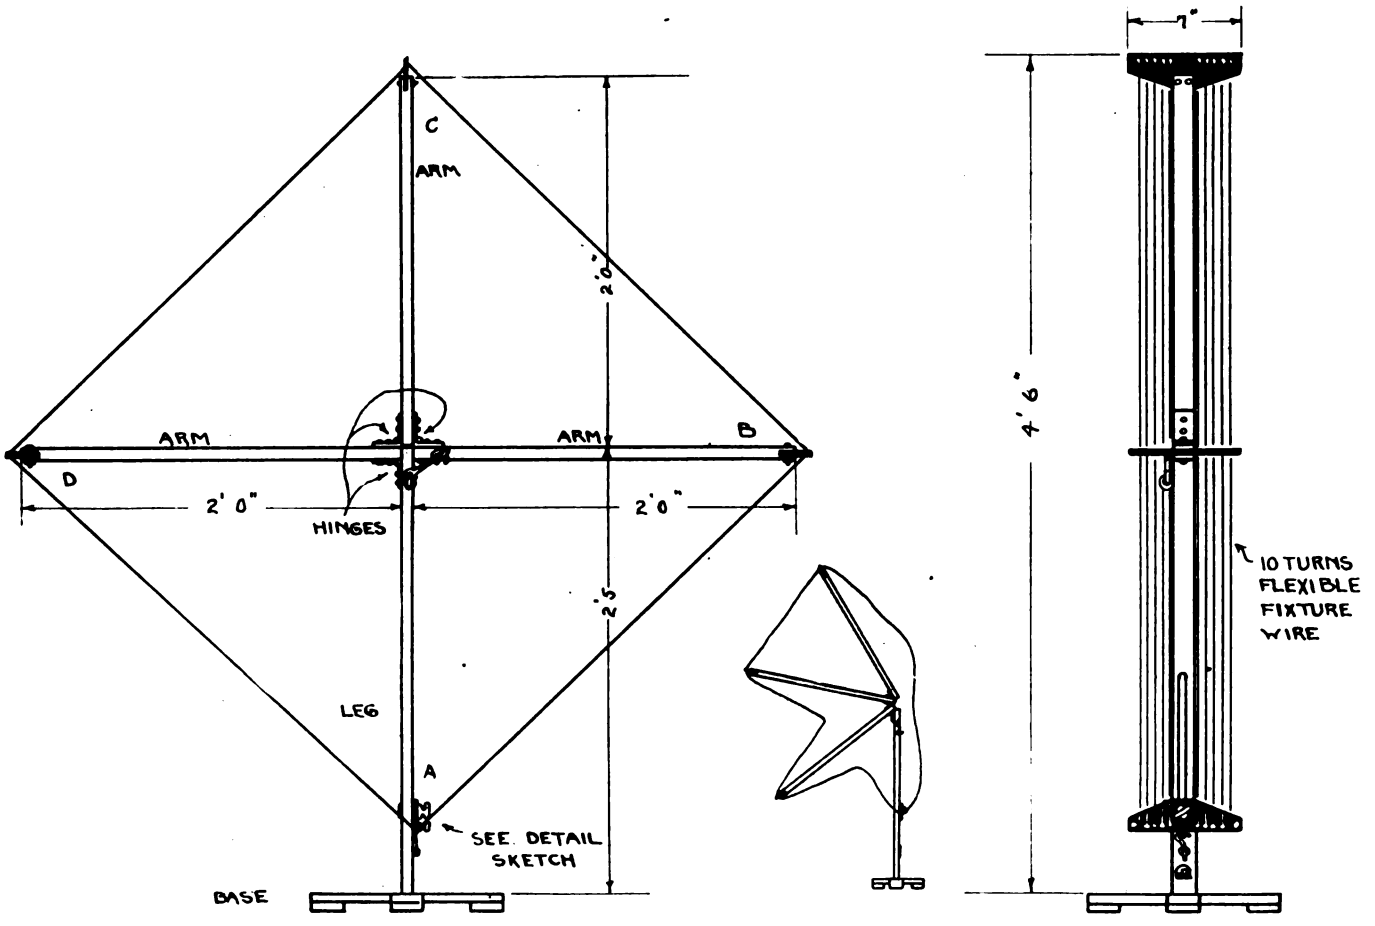

Fig. 1—The assembly of the collapsible loop. It has ten turns of No. 18 flexible fixture wire and folds in the manner shown in the smaller sketch.

Well, here it is. The folding loop antenna described and illustrated in this article is just what you are looking for. When closed, it fits neatly into a canvas bag, and can be carried on canoe and hiking trips with no trouble at all. When open for business, it is in no way inferior to an outside aerial; in fact, if the set with which it is used is a single tube super-regenerator, or a single or multitube reflex circuit, it is actually preferable. When used in a circuit which employs a variable condenser to control the wave length, it is suitable for broadcast reception over the entire range of wave lengths now allocated to broadcast work. It is directional, of course, but not extremely so, and this loose characteristic makes it ideal for small pleasure boats, whose unsteady veerings would otherwise interfere with continuous reception.

inches wide and nine feet long. White wood is recommended, but if this is not obtainable, any soft and not too heavy wood will do. Soft wood is used because of the ease with which it is worked. Saw the nine-foot strip into four pieces, one 2½ feet long and three others two feet long. The longest piece of wood is the leg of the loop frame, to which the base is fastened and on which the other three lengths, called arms, revolve.

Riveted to the end of each arm is a spreader made of hard rubber, fibre, or any other good insulating material. Wood will do, provided it is ash or oak; otherwise a wooden spreader is very apt to split when subjected to the strain of repeated collapses while the loop

(*Continued on next page*)

Digitized by Google

(*Continued from preceding page*)

is in use. These three spreaders are immovable. There is a sliding spreader, however, attached to the leg, and this has its peculiar use in slackening the turns whenever the loop is to be folded.

The hardware needed in constructing this portable loop consists of three suitable hinges, two hooks and eyes, a thumb screw, a number of copper rivets, six 8/32-inch brass bolts, a ¼-inch bolt with washers and nuts, and two brass or copper plates one inch square. The use and place of all this material is apparent from a study of Fig. 1, which is an assembly view of the completed antenna, but they will be mentioned again in detail as the description progresses.

The four spreaders are all of the same dimensions, two inches wide by seven inches long. The fixed spreaders are mortised into the end of the three arms, and are fastened there by two 8/32 brass bolts. (See Fig. 2.) Ten holes are drilled in each spreader, five on each side of the frame arm. The first hole is drilled ½-inch from each end, and the others at ½-inch intervals. These holes should be large enough to take the wire used in winding the loop, which in this case is No. 18 flexible fixture wire, braid insulated.

The details of the movable spreader are given in Fig. 3. Like the fixed spreaders, it has ten holes spaced ½-inch apart, and in addition, two others to take the two binding posts needed. On its lower edge it has a small eyebolt by which it can be hooked down into place. The slot in which the spreader slides up and down is ⅜ of an inch wide, and is cut in the wide face of the leg from just above the hook to a point 14 inches high. A thumb screw guides the motion of the spreader in this slot and also tightens it wherever needed.

The leg is fastened to the base by a ¼-inch bolt inserted up through the base and into the end of the leg. A hole is drilled and its lower half flattened out, so as to permit a wrench grip on the nut while tightening up. The base itself is merely two strips of wood dovetailed at the center and fitted with blocks two inches square at the ends.

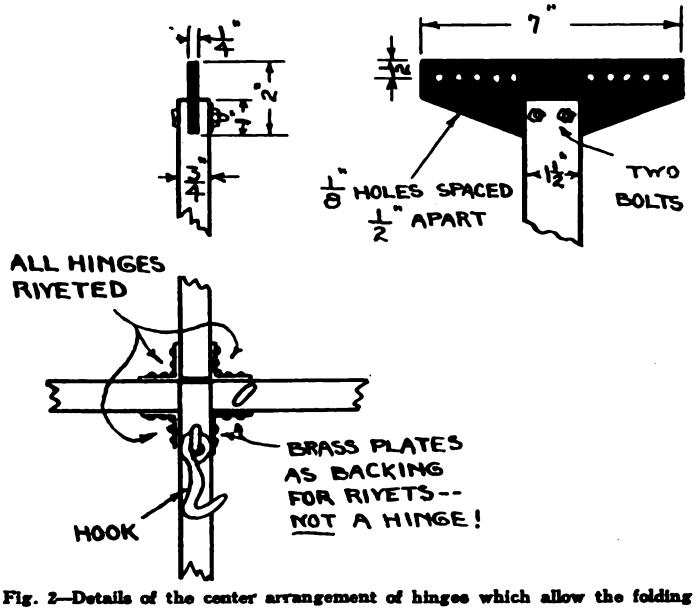

Fig. 2—Details of the center arrangement of hinges which allow the folding of the arms.

When the leg and arms are ready for assembly, hinge them together at the center as shown in Fig. 2. This is the most important detail of the whole job, for most of the loop's sturdiness depends upon the thoroughness with which the center arrangement of three hinges and one hook is carried out. The hinges should be riveted and not screwed to the ends of the arms. Where there is no metallic backing for the rivets, supply the brass plates as shown. The leg should project beyond so that its end is on a level with the upper sides of the cross arms. This allows the leg to act as a check upon the hinges. The hook is to hold the three arms in place after they are spread out.

The loop is wound with 10 turns of No. 18 insulated fixture wire. Fixture wire is flexible and therefore is readily adaptable to the needs of a folding loop. To wind properly, unhook the movable spreader from its final position and make it fast about one inch above that position. Take one end of the fixture wire through the first hole, connect that end to a binding post and wind the other around the loop, taking the entire amount of wire through each hole in turn. This takes some time and patience, but when finished, has its advantages, especially in this case, where the collapsible

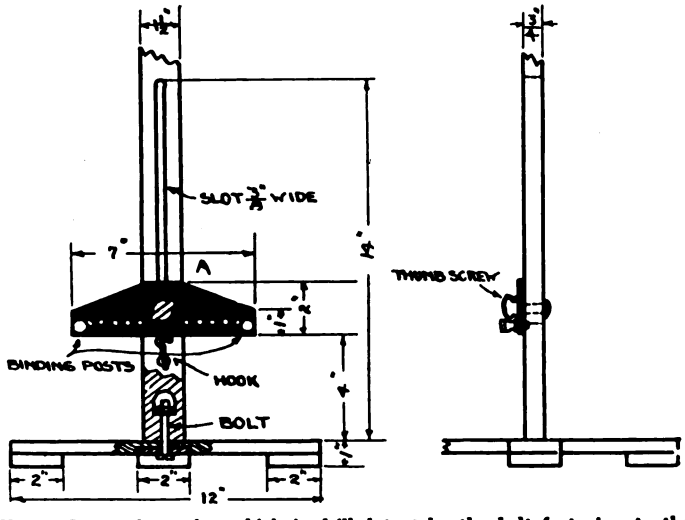

Fig. 3—Lower frame leg which is drilled to take the bolt fastening to the base. It is slotted so that the spreader can be moved up and down as required.

feature is so important. Connect the end of the last turn to the second binding post, and as you force the movable spreader to its hook again, you take all the slack out of the turns and the result is a very neat and attractive solenoid loop.

At this stage of the construction, try to fold up the antenna, and you will discover at once the reason why the lower spreader is movable. The turns must be slackened up considerably before arm B will swing alongside arm C, and this slackening is done by raising the movable spreader. The loop is folded as indicated in the small sketch in Fig. 1, and a leather strap is put around the four lengths to keep them together.

The particular loop described is somewhat of an antenna. It stands 4½ feet high and takes 120 feet of wire. With it, a single tube set can be operated satisfactorily for local and moderately distant work, but if the amateur is thinking of taking along a three or four tube set, either standard or special circuit, the loop can be cut down to half the size. In such case, of course, the features of the construction would be in no way altered.

The Radio Wise Man

THERE is a man in our town and he is wondrous wise;
He sits before a knobby box and pulls music from the skies;
He fools around with wires and tubes and other funny things,
And when he gets quite through with it—dad blame it all, it sings!

A Fine Portable One Tube Reflex Set

By W. S. Thompson, E. E.

WHEN spring arrives and summer is near at hand, there are always some "old-timers" who advise the radio fan to put aside his receiver until the cold weather again puts in an appearance. This advice, although well meant in the majority of cases, leaves a wrong impression with the inexperienced. Reception during the summer is not equal to that during the winter but there is no reason for setting aside the pleasure of tuning in stations just because the atmosphere is not absolutely clear of noises. In fact, the writer believes, the summer is the time to get the greatest pleasure out of radio. Imagine yourself floating along in a canoe and carrying with you a complete receiving set to supply music suitable for the occasion. And again, it is in the summer that we usually lack amusement in the form of plays, opera, etc., for their season is in the winter. In the summer one goes on a vacation back on the farm, to the mountains or to some other place which usually does not have very many facilities for amusement during the evenings. Then it is that the radio set comes into its own.

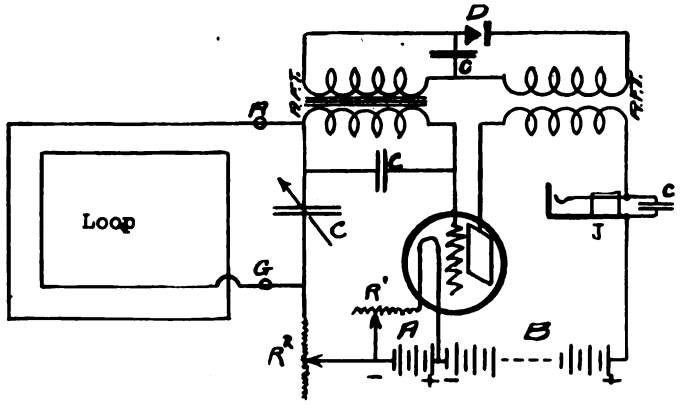

Fig. 1. Single tube reflex circuit used in the compact receiver. With a sensitive crystal detector this circuit is equivalent to a three tube set.

For summer reception there are several pointers regarding antennae to be kept in mind if the best reception is desired. Atmospherics are, of course, the biggest obstacle to overcome, but if one uses a loop or a short, low antenna such as can be put up in a half-hour or so, reception can be made remarkably clear. For an antenna a single wire 50 feet long stretched from the top of a tree to one's camp or house will serve remarkably well. A loop, such as described herein, can also be used and carried about with very little difficulty.

A few years ago when dry cell tubes could not be obtained, the vacationer usually left his radio set behind unless he owned a truck to take the necessary storage battery and plate batteries with him. However, today there are several tubes on the market which require only one dry cell for filament lighting so there is no reason for leaving a receiver behind because a storage battery is unhandy. The dry cell tubes are very efficient detectors and amplifiers, and can be depended upon to give just as fine reception as the larger tubes, so any one contemplating building the set described below may feel sure that he will have a really fine one tube portable receiver.

One of the most popular circuits which has recently been called to the attention of the public is the one tube reflex. This is a remarkable circuit and gives wonderful reception over long distances. Due to these fine qualities the writer has incorporated it into a very convenient outfit which ought to enable any experimenter to have music wherever he goes. Fig. 1 shows the wiring diagram for this portable set connected to a loop. The parts are lettered and are as follows: C—Three mica condensers 0.002 mfd.; C1—Variable air condenser 0.0005 mfd.; R1—Filament rheostat; R2—Potentiometer 400 ohms; J—Jack for phones; D—Crystal detector (synthetic); A-B—Batteries.

The potentiometer should be non-inductive such as the carbon pile type which is on the market. A wire potentiometer usually has its turns wound in the form of a coil so that any adjustment will change the inductance of any circuit in which it is connected. This is undesirable because it requires a readjustment of the tuning control. The purpose of the potentiometer is to suppress oscillations. After a station has been tuned in the potentiometer is adjusted much the same as the tickler coil of the regenerative receivers; that is, until the signal strength is maximum without distortion.

The crystal detector D is specified synthetic because there are some crystals sold today which are sensitive all over their surface so that there is no necessity for critical adjustments trying to find a sensitive spot. Due to this fact a permanent setting can be made and not be again touched for quite a while, depending upon the care with which the set is handled. The parts of the circuit marked A and G should be connected to a jack so that the loop may have its leads connected to the set by plugging in this jack. By this means attaching the loop may be made very convenient and allows for connecting an antenna and a ground to the circuit. If an antenna is handy or if the builder puts one up, it can be plugged in the same as the loop, providing a separate inductance has been hooked in series. This inductance may be a honeycomb coil, a variometer or any form of inductance. A honeycomb coil can very easily be carried in the case for there is ample room for one or two.

Fig. 2 shows the front view of the set when the hinged cover is open. The casing can very easily be made by anyone handy with carpenter's tools for the joints do not have to be dovetailed nor does the set have to look pretty. If care is taken to sandpaper well before varnishing, the casing will give a neat appearance, even though it is not made by a cabinet maker. As will be noted from the dimensions given, the wood specified throughout is ¼-inch thick, so the dimensions will hold only if this size is used. The cover is hinged to the cabinet by two small inexpensive brass hinges which can be purchased at any hardware store. Inside this cover is a handy place for maps and other papers the vacationer may carry. Ample space has been allowed for four small size B batteries, although this number is not absolutely necessary. By cutting the number down to two or three, a couple of honeycomb coils may be carried in order to increase the wave length range of the set, although, as it stands, all the broadcasters may be tuned in. The phones may be carried in a space provided for them so that every item necessary for reception can go with the set.

Fig. 3 is a top view of the set, giving some idea of the arrangement of the parts back of the panel. The parts are all lettered to correspond to the lettering of Fig. 1, making it difficult to go wrong in the wiring.

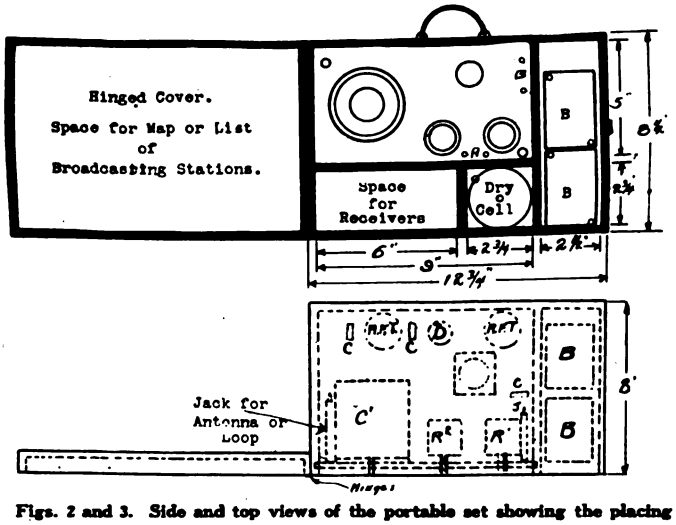
(*Continued on next page*)

Digitized by Google

(Concluded from preceding page)

In constructing the set a hinged door should be made over the tube socket to allow replacing of burnt out tubes or an adjustment of the detector D. This door may be just large enough to allow the hand to go in, but the whole top may be hinged if so desired. In any event, a catch of some kind will have to be made to keep this door shut. A hook which fastens over a small brass screw will do very well for both this door and for the hinged cover. The condensers C are held in place by the wiring so that no special mounting is necessary. When building the set the panel and the partition below it should be left out until the last of the assembly. The partition acts as the base for the apparatus so that all the wiring and assembling can be done on the panel and the base before placing in the casing. After the assembling has been done, the panel and the base should be put into place and fastened there with brass screws. All the joints of the case should be made using brass screws, thus making a very neat appearing job.

Fig. 4 shows a loop which may be carried with the set for it can be folded up and removed from the base. No dimensions are given on the drawing for they will depend upon the size loop the builder wishes to make. The square formed by the wires should not be less than eighteen inches for good reception and not more than thirty-six inches for good portability. A very convenient and efficient loop may be made by having the cross pieces eighteen and nineteen inches long, the longer one being vertical. The cross pieces may be made from one-half inch by one-half inch wood, being sure that it is hard and well seasoned. The bottom of the vertical piece should be rounded and fitted snugly into a hole in the base, allowing the removal of the base at any time. A good base may be made from a piece of wood seven inches square by one inch thick,



Figs. 2 and 3. Side and top views of the portable set showing the placing of all apparatus. A set similar to this can easily be taken anywhere you go, as it is self-contained.

drilling a one-half inch hole in the center for the loop standard. At the point where the two cross pieces intersect, each should be sawed half way through one-half inch apart, as shown in Fig. 4. This allows the two pieces to cross and still have their sides flush. They should be held together with a small brass bolt with a wing nut. The wires are held in slots cut at the ends of each cross piece one-fourth inch apart and slanting towards the center. As shown in Fig. 4, the slots should be cut just deep enough so that there is no chance of the wires coming loose when the loop is in use. For the size loop specified, eighteen turns of wire will allow the set to tune in all broadcasting stations except some of those operated by the government.

When the parts of the loop are finished, they should be assembled and the wire wound in the slots, fastening each end to the bottom of the vertical cross piece. These two leads may then be attached to a telephone cord and the cord to the plug which goes into the loop jack of the set. To carry the loop all that is necessary is to remove the bolt at the center, spring the two cross pieces apart and then turn them until they are parallel, making a convenient bundle. During this turning process, the wires are very liable to come loose

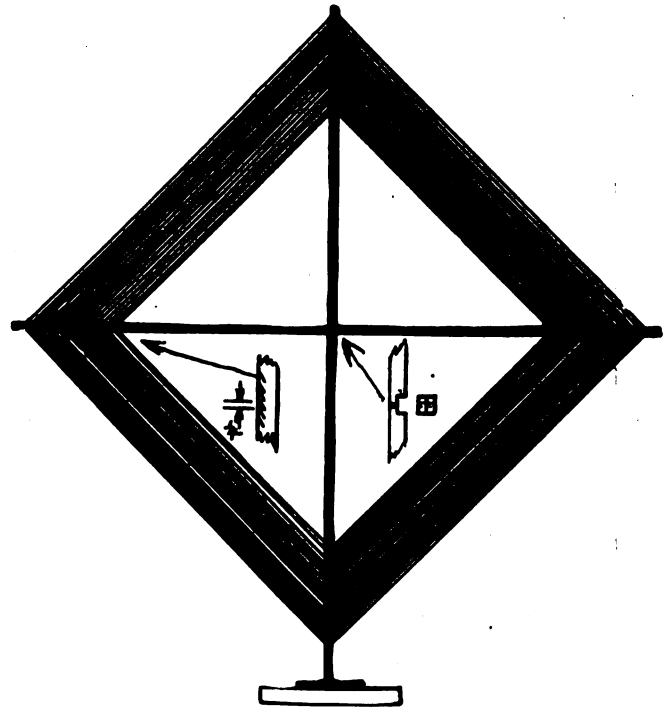


Fig. 4. Collapsible loop used with the portable receiver.

from the slots so a thin piece of insulating material should be fastened over them, preventing any wires from slipping out. Precaution must be taken to prevent the wires from tangling up and kinking. If a stranded cable is used, this difficulty is avoided because the wires may be tied firmly to the rods without danger of permanent kinks.

With this set one may have entertainment this summer, no matter where one may be, and it is the hope of the writer that nobody will find it too much trouble to build.

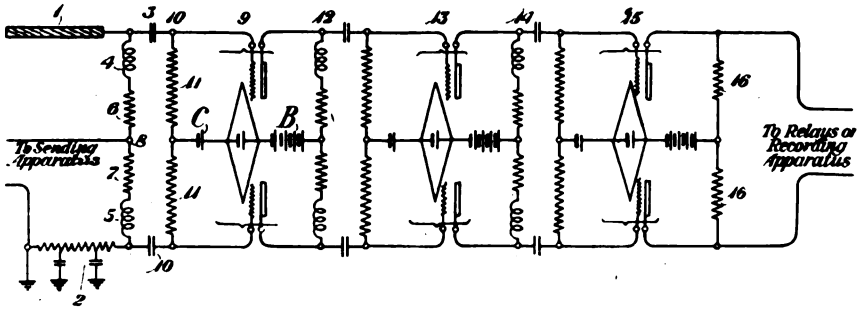
Latest Radio Patents

Receiving Circuits for Weak Signal Currents

No. 1,450,980: Patented April 10, 1923. Patentee: John R. Carson, New York City.

This invention relates to signal transmitting systems and is concerned especially with the receiving end of transmission lines in which there is a considerable amount of distortion and attenuation, the original form of the current impulses though adding to the attenuation, and then to amplify the faint but corrected impulses by an amplifier of the thermionic type in which large amplification, without substantial distortion, can be secured. It has also been proposed to connect



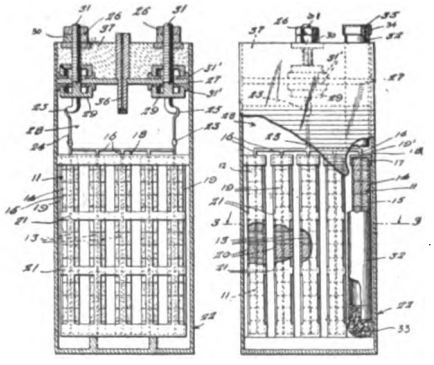
John R. Carson's method of boosting weak currents in retransmitting signals.

as in long submarine cables. It is well known that in signaling over lines of the character mentioned, the speed is very limited because of the characteristics of the line and many efforts have been made to overcome this difficulty. It has recently been proposed to combine with circuits of this sort correcting networks which restore, to a considerable extent, correcting networks and amplifiers alternately in the circuit so that both the correcting and amplifying are done in successive stages. By this means impoved results are obtainable. It is the object of the present invention to provide an efficient circuit of this type suitable for duplex operation. The principle involved can be applied to radio or line work.

Storage Battery

No. 1,451,347: Patented April 10, 1923. Patentee: William H. Thorpe, Mount Vernon, N. Y.

This invention relates to small storage batteries and its object is to provide a comparatively inexpensive storage battery suitable for delivering small current outputs, but having a large ampere-hour capacity for a given weight of active material, a minimum amount of local action and a reasonable length of life, that is,



Battery delivering small current out-put but having large ampere-hour capacity.

cycles of charge and discharge, and a minimum amount of deterioration while standing idle. Also included in this invention is an improved method of filling the battery with water or electrolyte and an improved method for the prevention of terminal corrosion.

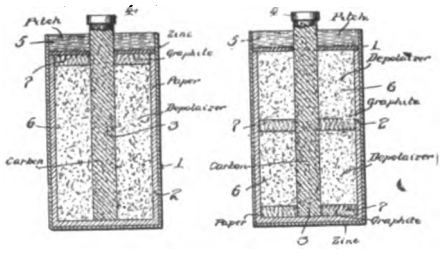
I have herein described one embodiment of my invention which is the best of which I am at present advised, but this embodiment is used in an illustrative sense and not a limiting one for obviously many embodiments can be devised which will be within the spirit and scope of the invention.

High-Power Dry Battery

No. 1,452,230: Patented April 17, 1923. Patentee: Alfred A. Wells, Montclair, N. J.

This invention relates to dry batteries and relates especially to batteries of the Leclanche type composed of a zinc cup having a central carbon pencil or electrode surrounded by a depolarizing mass of carbon and manganese dioxide, but the invention is not wholly restricted to the particular type of battery herein described for illustrative purposes.

In the present invention it is the object to produce a battery having a high amperage or current output and also in some cases to secure a higher voltage.



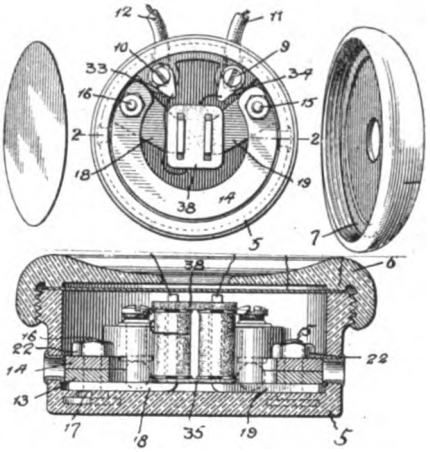
New method of constructing a high power dry cell.

The invention as carried out in its preferred form involves the introduction into some portion of the depolarizing mass of a layer or restricted zone of graphite, carbon or similar conducting material, preferably without any manganese dioxide or other depolarizing agent present (although the latter may be introduced in case the conductivity is not materially affected). The restricted zone of conducting material, which will be hereinafter referred to for illustrative purposes, simply as graphite, may be a layer thereof one-eighth to one-fourth inch or more in thickness, preferably extending from the carbon electrode or pencil to the paper, cloth or other insulating material present between the depolarizing mass and the zinc container. Preferably the layer of graphite is placed over the depolarizing mass and is securely tamped in place, but it is also possible to have such layer in the middle or at the bottom, or elsewhere, in the depolarizing mass. Delaminated graphite is especially useful for the purpose and although of a bulky character, on pressure it packs to a dense mass, appearing almost like a solid block of graphite, and this material fills in compactly around the carbon pencil, making a continuous conducting mass between the latter and the zinc electrode.

Telephone Receiver

No. 1,452,334: Patented April 17, 1923. Patentee: Charles T. Baisley, North Edgecomb, Maine.

This invention relates to telephone receivers, and particularly to receivers of the watch-case type. The particular ob-



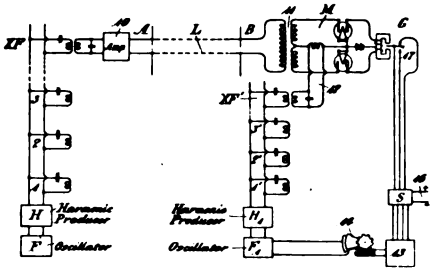
Improved method of constructing a telephone receiver.

ject of my invention is to provide a receiving magnet unit of improved construction which facilitates its manufacture and its assembly with the related elements of the receiver.

Synchronizing System

No. 1,450,966: Patented April 10, 1923. Patentee: Herman A. Affel, Brooklyn, N. Y.

This invention relates to means for producing synchronism and isochronism between the alternating currents supplied



Means of syncronizing alternating currents independently supplied.

from independent sources. One of the features of the invention resides in the provision of means whereby the current supplied from one alternating current source may be automatically maintained at the same frequency and in the same phase relation with respect to currents supplied from another source. Another feature of the invention resides in the provision of means whereby the frequency and phase angle of a locally supplied alternating current adapted to be used in connection with the production of carrier frequencies for a multiplex system may be maintained.

THINK of your Radio receiving set as a kind of camera whose "film" is sensitive to *sound* waves instead of *light*.

Developing this "film" into real "sound pictures" is the whole art of Radio usefulness and enjoyment.

For this, no apparatus has ever been evolved which gives results equal to those produced by Magnavox Equipment.

R2 Magnavox Radio
(With 18-inch horn)

This instrument is intended for those who wish the utmost in amplifying power; for clubs, hotels, dance halls, large audiences, etc. It requires only .6 of an ampere for the field. Price **$60.00**

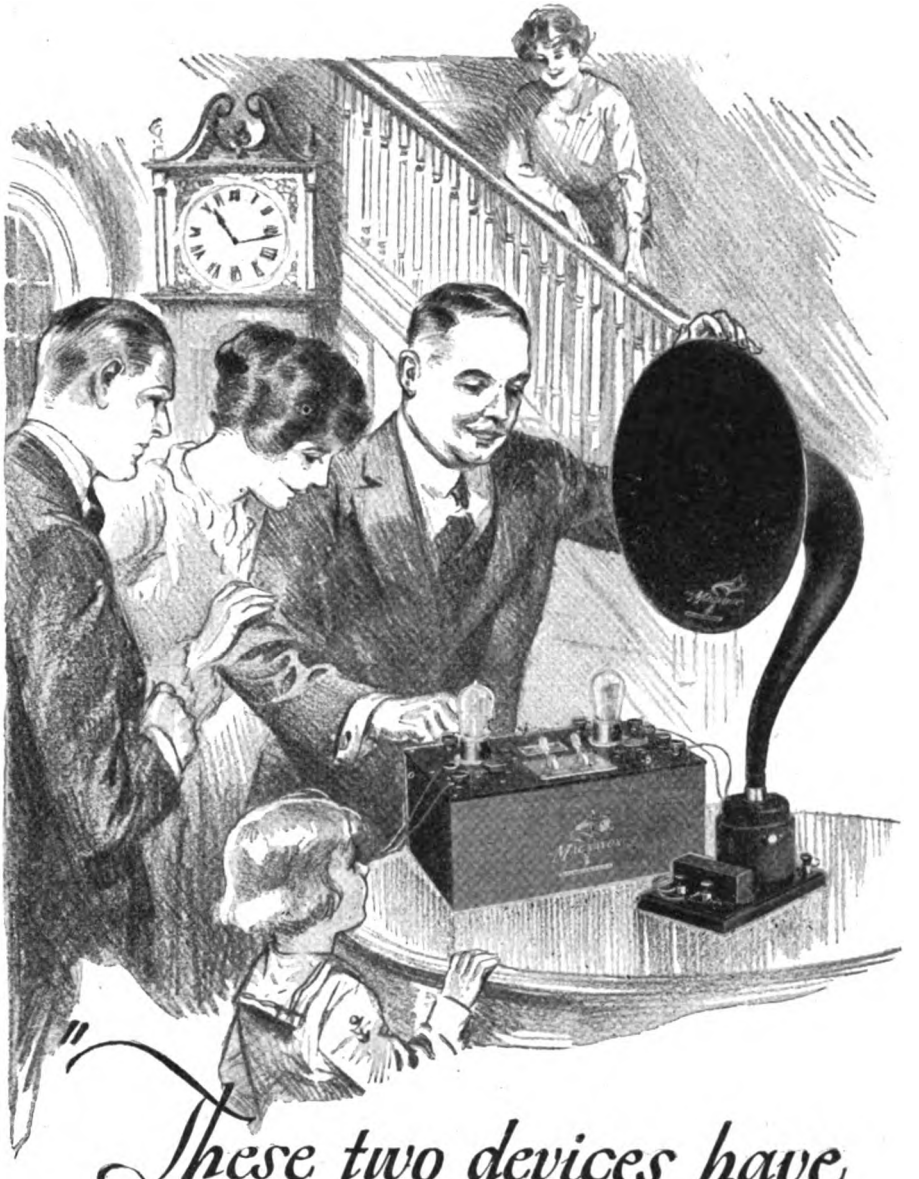
R3 Magnavox Radio
(With 14-inch horn)
As illustrated

The ideal instrument for use in homes, offices, amateur stations, etc. Same in principle and construction as Type R2.
Price **$35.00**

Model C Magnavox Power Amplifier
As illustrated

For use with the Magnavox Radio and insures getting the largest possible power input.
AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Reproducers and Power Amplifiers can be used with any receiving set of good quality. Without Magnavox, no receiving set is complete.



"These two devices have revolutionized Radio"

The Magnavox Reproducer and the Magnavox Power Amplifier

THE efficiency of Magnavox Radio apparatus is best realized by comparison with other instruments constructed on less modern scientific principles.

Magnavox products can be had of good dealers everywhere. Send for copy of unusual booklet.

Answers to Readers of Radio World

In RADIO WORLD *for March 17 you published an article with a circuit diagram by Mr. Shideler. I have constructed the set and have tried to get it to work but without success. All that I can seem to get is a persistent hum in the receivers. This is more insistent when I hold my thumb on any of the switch points and pull the switch arm away from the contact. I am using 16½ to 22½ volts on the plate and outside of using No. 20 instead of the No. 26 wire I have made it exactly as described. What is my trouble?—Edward MacDowell, 450 N. Queen Street, Lancaster, Pa.*

From your description and the fact that you get the hum even when your primary is out of the circuit, you evidently have a broken line somewhere. Go over your wiring very carefully and trace all your lines. Examine the connections on the tickler and see that everything is connected properly. This insistent hum is an indication of a break somewhere in the circuit. Find the break and you will find your trouble.

* * *

I constructed the set described in your issue of April 7, by F. J. Rumford and followed all his directions, but cannot get rid of a whistle that is very noticeable and sometimes is unbearable.

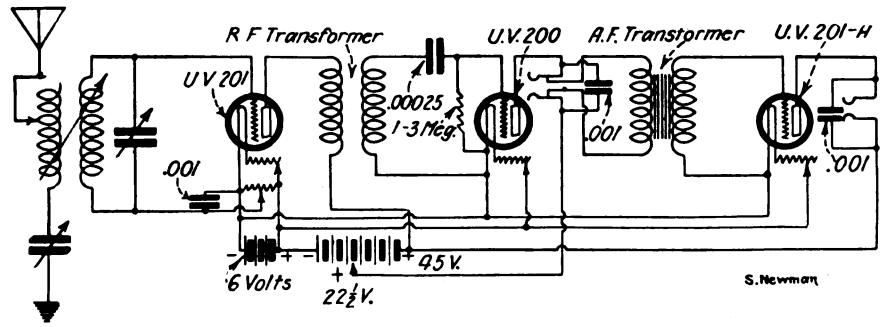
I get local stations, but there is always this steam whistle blowing in the phones. How can I remedy it?—Walter Moore, 14 S. Spring Ave., St. Louis, Mo.

Do not burn your tube so high. Cut down on the filament current. You are forcing your tube. Use a larger grid condenser (.0004 or .0005). Reverse the leads on your tickler coil. Decrease your B battery and see if that doesn't stop it. Jump the minus B across to the plus of the A instead of the minus as you have shown it in the diagram.

* * *

Kindly publish a diagram for one stage of radio-frequency, detector and one stage of audio-frequency using the following apparatus: One vario-coupler, one U. V. 201A, one 200, one 201, one 1714 radio-frequency transformer, one 712 audio-frequency transformer, two vernier rheostats, one straight rheostat, one 200 ohm potentiometer, three Dubilier .001 fixed condensers, one 17 plate variable, three sockets, two jacks, phones and batteries. What will I be able to receive on such apparatus and the circuit you are giving me?—John Bakersmith, 3202 R. I. Ave., Mount Rainier, Ind.

The diagram you desire is published herewith. It is impossible to state definitely the range of any receiving set, as there are too many conditions that are to be dealt with in the reception.



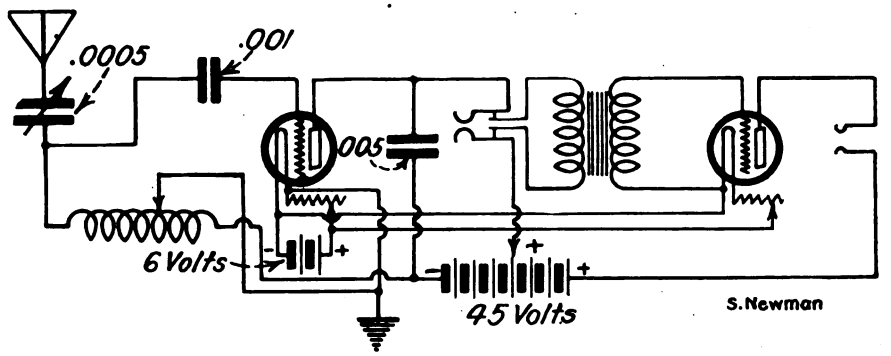
Hook-up published in answer to a request by John Bakersmith using the apparatus called for by him. The first and second rheostats are vernier and the audio-frequency amplifier rheostat is straight control. The potentiometer can be either 200 or 400 ohms.

Kindly send me, or publish, a circuit diagram for a 10 watt CW or phone set that will give me good results.—H. G. Armstrong, La Tuque, Quebec.

We refer you to the article published in RADIO WORLD for May 26 by R. W. E. Decker on a low power two tube transmitter.

* * *

Kindly give me a hook-up embodying one stage of audio-frequency with the "pup" circuit. Does the antenna condenser increase or decrease the wave length when increased from zero to full capacity?—Edw. H. Bitner, 1510 Catherine St., Harrisburg, Pa.



The "Pup" circuit with one stage of audio frequency amplification requested by E. H. Bitner. If the new U. V. 199 is used, the second tube should have a grid bias battery in the grid lead for proper operation.

The circuit you want is herewith published. As you increase the capacity you increase the wave length. When the condenser is at zero the lowest wave lengths will be responded to. When at the full capacity, the highest wave length will be responded to.

* * *

I recently purchased a John Firth five-tube set—two stages of radio-frequency, detector and two of audio. There are only two rheostats controlling the five tubes. One is marked R. F. and the other Det. There is no rheostat for the audio-frequency, but the last two tubes are controlled by an independent switch. Is this correct? Should not there be some control for the last two tubes?—I. F. KKrause, 350 Broadway, New York City.

There is no mistake in this circuit. It is designed to operate as either two stages of radio-frequency and detector, or radio-frequency, detector and two of audio. The fact that there is no control for each separate tube is just to simplify the controls. Because of the fact that audio-frequency is not critical, there need not be a filament control to these two tubes.

What are the sizes of the coils used with A. Riddel's DX hook-up published in RADIO WORLD *for March 10?—J. S. McKibben, 3522 Washington Ave., St. Louis, Mo.*

You can use 35, 50, 75 DL coils with this circuit using the 50 as primary, the 75 as secondary and the 35 as tickler. This will allow you to get the broadcast program if your antenna is not too long. It would be well to get a set of DL coils of the following sizes in order to enable you to experiment and find out just which suits your needs best for each particular wave. 25, 35, 50, 75, 100.

I recently constructed one of the sets described by W. S. Thompson in RADIO WORLD *for March 3. I am referring to diagram No. 3 on page 4. I have had excellent results with it, but desire to put in permanently a loose coupler and antenna and ground, as I cannot get sharp enough tuning with a loop. I sometimes have two and three stations on together. I can also take the catwhisker off the crystal and hear signals. Why is this? Will I be able to use the new U. V. 199 tubes with this circuit successfully?—J. D. McGee, 214 East 11th Street, New York City.*

You can incorporate the loose coupler and antenna and ground by hooking the primary up as usual and putting the secondary leads in place of the loop leads. A loop generally gives much sharper tuning than a vario-coupler or loose coupler because of its directive effects. Your set should not operate when you remove your catwhisker. You must have leakage somewhere. It often occurs in reflex sets that one of the tubes can be removed and the set will function at a very low state of efficiency, but the fact that you can get signals without your detector proves that through some channel you are using one of your tubes as a detector. Examine your leads and see that they cross at right angles, and are well insulated. Do not bunch them.

* * *

Enclosed please find picture of a set. Kindly let me know what type of circuit it is and also just what apparatus I would need to construct it.—Edward Weick, 115 Striker Ave., Woodside, L. I.

The set shown is a straight three step radio, detector and two steps of audio-frequency. The apparatus necessary to construct it would be six tubes, six sockets, three radio-frequency transformers, two audio-frequency transformers, one grid leak and condenser, five fixed condensers (two .0005, two .001 and one .00025), necessary binding posts and batteries.

Play These DX Nite Owl Records on Your Radio

Get Out Your Glasses and Adding Machine

From Leland Whitelock, 400 Ninth St., Petersburg, Ind.

I HAVE seen many good records in your DX department and thought I would send in mine: KGW, about 2,500 miles; KMO, about 2,500 miles; KHJ, 1,775 miles; KFI, 1,775 miles; KOG, 1,775 miles; KWH, 1,775 miles; San Pedro, Catalina Islands, 1,780 miles; KZM, 1,335 miles; PWX, 1,325 miles; WKAQ, 1,325 miles; KDKA, WGY, WOS, WPA, WEAH, WBAK, WWJ, WAH, WDAJ, WBZ, WLAG, WJAG, KSD, WOZ, WDAP, WCAU, WKAA, WIAH, WDAF, 2XI, WLK, WHAM, WIAO, CFCE (about 1,300), WGM, KYW, WOAF, WBT, WJT, WJK, WHAS, WBAP, WMAQ, WJAX, WFO, WGAS, WHB, WOI, WOAI, WCAP, WLAT, WGR, WOH, WSX, WJZ, WOR, WOO, WAAY, WSB, WJAZ, WMAZ, WHAJ, 5ZA (about 1,500), WCX, WOC, WWI, WIP, WBAY, WLAP, WLW, WGAV, WMAK, WMAV, WCK, 8YM, WOK, WCAF, WDZ, WJAP, WKAM, WLAL, WHK, WKN, WPAL, KFAF, WEAB, WBL, WHAI, WBAV, WDAO, WEAF, CJCG, KLZ, 5ZY, WFAA, CFCA, NOF, 8XS, WSY, 2XB, WEAY, WNAY, WGF, 3JM, WAAP, WGAQ, WJAM, WBAH, WPAC, WNAT, WCAE, WCAV, WMAT, WAAF, WDAA, WNAL, WIAC, WCAG, WDAY, WDAG, WLB, WRP, WKAS, 9ZAF, WFAT, WQAA, WOAL, WIAR, WMH, WOAA, WEAC, WEAO, WMAB, WOE, WEAS, WCAL, 8XR, 5XAJ, WJAN, WNAD, WCAS, WPAD, WIAY, WTAW, WCM, KOP, WWZ, WIZ, WMAF, WAAC, WGAY, 4EB, WOQ, 4ET, 2XAP, WMAJ, WKY, WRW, WFAN, WIAS, WHAB, WAAR, WGI, WOAN, WOAV, WAAH, WNAC, 8XH, WPG, WJAF, WVP, WAAW, WOAW, WHAH, WRR, WDAR, WTAS, KFDL, WWAY, WHA, WDAL, CFCF, WHAZ, WAAK, WCAY, WBAA, WBAO, 8XT, WCAQ, KFFQ, WQAQ, WGV, WEAN, WGAM, WCN, WAI, WIAX, 9DMB, 9DIS, 9BYT, 9KS, CKCE, WFAV, KFDB (about 2,000 miles), WABA, KFGC, 9EJB, 9DLR, WPAB, WDAH, 9DZM.

This list of phone stations includes 211 stations in 36 States, three provinces in Canada, Cuba and Porto Rico. All these stations have been received since December.

The receiver is a home-made single-circuit set with detector only. The type C 300 detector tube was used.

Come on in, the water's fine. (This is for you other DXers.)

* * *

And Still They Come

From Gerald R. Duncan, Fayette, Iowa

IN response to your request for DX results, I am herewith sending mine. I am using Mays' capacity coupled circuit.

I have heard fifty-eight stations since hooking it up. I heard the following in one evening, in about four hours' time: WHAZ, WOC, WMC, WBAV, WSY, KDKA, WCAE, WBAM, WSD, WSAA, WOS, WGY, KDYS, WCAS, KFAF, WLW, WBL, WBAP, WGM, WLAG, WDAJ, WBA, KFEL, KFI, KHJ, KGW.

The limits of the set so far has been KGW, WOR, WSAV, WOAI, CHCQ, WDAJ, CFCA.

My aerial is two wires 65 feet long, thirty feet high, stretched between two trees. The only change I have made in the hook-up given by May is to put a 17-plate vernier in series with the aerial.

THE Editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

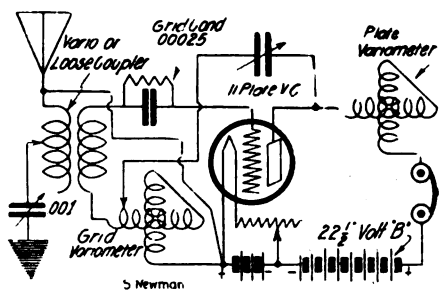
Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

Here's One to Try Out

From Myrle Wood, Star Route, Rhinelander, Wis.

I AM sending you a hook-up that I am using, and I am getting some remarkable results with it. With this hook-up I have heard nearly 100 stations. The most distant ones are: PWX, Havana, Cuba; WKAQ, San Juan, Porto Rico; KHJ, KFI, KDZF, Los Angeles, Cal.; KFC, Seattle, Wash.; KGW, Portland, Ore.; WPAT, El Paso, Teas; WOAI, San Antonio, Texas; WFAA, WGR, Dallas, Texas; WBAP, Fort Worth, Texas; KFAF, Denver, Colo.; WSB and WGM, Atlanta, Ga.; WDAJ, College Park, Ga.; WEAF, New York City; WGY, New York.



Myrle Wood's one tube hook-up. Note the connection on the grid variometer. Tap off on the outside connection of the stator and bring it around to the plate variometer—and, "Oh, what a grand and glorious feelin'!"

WOC, WCX and WGY can be heard all over the room some nights on the one tube. The tube is a WD-11. The wire running from the aerial to the positive of the dry cell (A battery) does away with a lot of capacity effect. When connecting up the 11-plate variable condenser between the two variometers be sure that one wire from the condenser connects with the plate wire that runs to one side of the variometer and the other wire from the condenser should be connected to the side of the variometer that the secondary wire is connected to. Very fine tuning can be accomplished with this circuit, and it is very good for DX work. I have heard WLAG, Minneapolis, with no aerial and no ground and I hear WSB, Atlanta, Ga.; WJZ, Newark, N. J., and others on a loop aerial. And I have heard as far as Fort Worth, Texas, during the day. I am a steady reader of your magazine and think it is fine.

* * *

You'll Have to Step Some to Catch This Boy—I'll Tell It!

From Don Smith, Graford, Texas

I AM a six months' crystal fan. My set consists of one two-slider tuner, crystal detector, and one pair 3,000-ohm phones. My aerial is a single wire 100 ft. long and 30 ft. high. I have a total of 23 stations, the farthest being KHJ at Los Angeles, a distance of 1,250 miles, which I believe is not bad for a crystal. My single night record is 11 stations: WMC, Memphis, Tenn; WOS, Jefferson City, Mo.; WOAI, San Antonio, Tex.; WEAY, Houston, Tex.; WMAB, Oklahoma City; WHAN, Wichita, Kan.; KSD, St. Louis, Mo.; WHA, Madison, Wis.; WFAA, Dallas, Tex.; WDAO, Dallas, Tex.; WPA, Fort Worth, Tex.

* * *

Another Nice Record

From C. C. Barber, Villa Alta, Colonial Heights, Yonkers, N. Y.

BEING particularly interested in your DX page I thought I would send in my record and would be greatly pleased if you would publish it. The hook-up that I am using is a modified Colpitts with variometer tuner and a WD-11 tube. I have picked up Chicago and Atlanta on an aerial around the molding of my room.

The following is a list of the stations: WJZ, WOR, WAAM, WBS, WBAN, WEAF, WHN, WRW, WGY, WHAZ, WBZ, WGI, WIP, WDAR WOO, WCAE, KDKA, WBT, WMC, WNAV, KSD, WOS, WOC, WDAF, WAAZ, WPAD, WJAZ, KYW, WLAG, WWJ, CKCE, CHYC, CKAC, WLK, WLAK, WGR, WFI, WIZ, WBAA, WSB, WBAY, WFAF, and four amateur stations.

Another Golfer in the Rough

From C. L. Hobart Company, Grants Pass, Oregon

HAVING read in the radio journals of "Radio Golf" and on March 20th, as atmospheric conditions were favorable, decided to try it with the following results:

Station	Location	Miles away
BE1	Camp Lewis, Wash.	375
KSD	St. Louis, Mo.	1,825
KDYL	Salt Lake City	600
KQY	Portland, Ore.	250
KFI	Los Angeles	700
WHB	Kansas City	1,600
KHJ	Los Angeles	700
	Catalina Telephone	700
KZR	Bellingham, Wash.	450
KFAU	Boise Idaho	365
KFCF	Walla Walla, Wash.	365
KNT	Aberdeen, Wash.	325
WBAP	Fort Worth, Texas	1,600
WCX	Detroit, Mich.	2,125
WOAI	San Antonio, Texas	1,725
CHBC	Calgary, Canada	800
KFFO	Hillsboro, Oreg.	240
KWG	Stockton, Calif.	350
KMJ	Fresno, Calif.	500

19 stations. 15,595 total mileage.

Two hours and ten minutes, nineteen stations, with a total of 15,595 miles, from three points of the compass. Used a modified Flewelling "flivver" circuit with one peanut tube.

These One-Tube Babies Get 'Em!

From W. F. Gray, 5145 Terry Ave., St. Louis, Mo.

HAVING read the DX records in your magazine for some time I thought I would give you my list of stations.

These stations have been heard from January 1, 1923, to March 17. They are as follows: PWX, KHJ, KFI, WOAI, WFAA, WBAP, WCAR, WQAA, WIP, KDKA, WWZ, WGY, WCX, WWJ, WBAD, WLAG, WHA, WFAC, WBT, WGM, WSB, WDAJ, WDAP, WMAQ KYW, WBL, WAAP, WOC, WHB, WDAF, WHAH, WOS, WOAL, KZL, KFDL, WOR, WLW, WNAV, WMC, WHAS. Local—KSD, WCK, WRAO, WMAY.

The hook-up is a one-tube set, homemade.

Radio Literature Wanted

Manufacturers of and dealers in radio apparatus and accessories are notified that literature and catalogues describing their products have been requested, through the Service Editor of Radio World, by the following:

Frank Ameel, Jr., 88 Grand Ave., Mt. Clemens, Mich.
Ray McCarthy, 111 Cass Ave., Mt. Clemens, Mich.
Bud Prevost, 368 Cass Ave., Mt. Clemens, Mich.
Howard Smith, 982 State St., Appleton, Wis.
Radio Shop, 1070 Elizabeth Ave., Elizabeth, N. J. (Retailers and distributors.)
A. R. Reimsnider, Dorsey, Md.
Jas. H. L. Jewell, 76 Livingston Ave., Albany, N. Y. (Retailer)
K. D. Miller, Johnstown, N. Y.
H. L. Conrath, 355 North Craig St., Pittsburgh, Pa. (Wants a three tube receiver.)
Frank J. Franzreb, 132 Van Duzer St., Tompkinsville, S. I., N. Y.
John Vaughey, Sr., St. Marks Place, Tompkinsville, S. I., N. Y.
Chas. Enderes, 660 Bay St., Stapleton, S. I., N. Y.
Stephen Storey, 2221 Fairfield Ave., Fort Wayne, Ind.
W. B. Powell, Eustis, Fla.
Arthur O. Halley, 53 Thorndike St., Arlington Mass.
Herbert W. Jones, 85 Draper St., Dorchester, Mass.
Chas. Fisher, Box 492, Mitchell, Neb.
M. J. Geer, Box 62, Sabetha, Kan.
Harold Kutzley, 11 Twelfth St., Toledo, O.
Salamanca Electric Co., Inc., 12 Main St., Salamanca, N. Y. (Retailer.)
Chas. W. Gray, Brisben, N. Y. (Retailer.)
Chas. G. Rose, Post Office, Lorain, O.
John Orsznlak, 183 Goodyear Ave., Buffalo, N. Y.
Elmer Zimdors, 1060 Richards St., Milwaukee, Wis.
A. B. Watson, 2760 Cherry St., Kansas City, Mo.
Carolina Radio Co., 306 N. Tryon St., Charlotte, N. C. (Manufacturers, distributors and jobbers.)
Fred D. Alexander, P. O. Box 593, Pikesville, Ky. (Will open at once a radio and small specialties shop in Dayton, O.)
H. G. Bradford, 95 Hansel St., Atlanta, Ga.
William D. Snow, 303 Sherburne Ave., St. Paul, Minn.
George Slocomb, Engineering Dept., Southern California Edison Co., Los Angeles, Calif.
John F. McKiernan, 76 West St., New Haven, Conn.
Percy W. Shepard, New Albany, Pa.
Howard W. Root, Derby Line, Vt. (Will stock a line of radio supplies.)
A. G. Walden, Tech. Sgt., Q. M. C., Fort McPherson, Ga.
Dr. Frank Lamb Willson, 815 Hill St, Suite 704, Los Angeles, Calif
E. Eddy, 213 Grant Ave., Millvale, Pa.
Edward L. Fitzgerald, Hebron, Neb. (Intends to sell sets and parts.)
William O. Wulffe, Walcott Lathe Co., Jackson, Mich. (Is building sets for sale.)
Luman Long, 1003 Park Street, Rolla, Mo.
Thomas A. Moore, 557 Walnut Street, Elizabeth, N. J.
Jackson & Son, Como, Miss. (In market to buy set.)
T. J. Thompson, 301 West 110th Street, New York City. (Dealer.)

Brandes Add to Factory Space

C. BRANDES, INC., manufacturers of Brandes matched tone headsets, 237 Lafayette Street, New York City, have recently added another 5,000 square feet of floor space and a great deal of machine equipment to their assembly plant in order to handle the increase in business. Mr. Frederick Dietrich, president, states that the future seems to hold forth every prospect of a decidedly successful year.

Son of Theatrical Attorney Wins Radio Prize

ABNER H. BEREZNIAK, son of Leon A. Berezniak, prominent Chicago theatrical attorney, won first prize in a Chicago radio contest last week.

Station WPAD conducted by the Wieboldt Store, Chicago, announced that they would give five prizes to the five best entries submitted in what they called a "Radio Suggestion Contest." The people listening in were to send in suggestions for a contest which WPAD could use in the near future. The entries were to also include a means for distributing twenty prizes.

Young Abner, who is 17 and an ardent radio "fan," submitted his entry for a "Musical Memory Contest." His suggestion briefly was for WPAD to broadcast for two weeks previous to the night of the contest various classical and popular pieces. The night of the contest they were to broadcast twenty of the pieces which had been played before, picking these pieces at random, and the "listeners in" were to send in the names of the pieces they believed had been broadcast.

The unique part of his idea was that the answers were to be sent in in story or poetry form. The people submitting entries were to write up the names in some form which could be broadcast and make interesting "listening."

The prize he won was an Olympian phonograph donated by a Chicago musical store. The "Musical Memory Contest" is being broadcast this week over WPAD.

Of Interest to Dealers

THE New York Coil Company announces for distribution a new receiving set at a medium price, a new inductance switch and a new vernier condenser, all of which will go into quantity production at once to supply a demand created by the company's other well known radio products. New descriptive literature has been prepared and will be mailed upon request to the New York Coil Company, 338 Pearl street, New York City.

Radio Manufacturer Publishes His Own Music

AS a result of the controversy between the broadcasting stations and an association controlling the copyrights of certain musical compositions the Crosley Publishing Company, of Cincinnati, has just issued, in printed form, a copy of "Somebody Else Is Stealing My Sweetie's Kisses," which was made popular by presentation to radio audiences through broadcasting station WLW, of the Crosley Manufacturing Company, Cincinnati.

Wants Crystal Detectors

JAMES A. HAMILL, Mercer and Colgate Streets, Jersey City, N. J., informs RADIO WORLD that he is in the market for a considerable number of good crystal detectors of the fixed or semi-fixed type.

Policy Committee of the Radio Trade Association

President Henry M. Shaw, of the Radio Trade Association, 1133 Broadway, New York City, has appointed the following Committee on Policy of the association:

Raymond Francis Yates, Electrical Corporation of America.
Harry M. Konwiser, *The Radio Dealer.*
H. Gernsback, *Radio News.*
Roland Burke Hennessy, RADIO WORLD.

Questions regarding the policy of the association as brought up by individual members will be discussed by this committee and transmitted to the board of Directors for final decision.

Coming Events

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

NATIONAL ELECTRIC LIGHT ASSOCIATION, New York City, June 4-8, 1923; M. H. Aylesworth, executive manager, 29 West Thirty-ninth Street, New York.

PACIFIC COAST ELECTRICAL ASSOCIATION, San Francisco, Calif., June 19-22, 1923; S. H. Taylor, secretary, 527 Rialto Building, San Francisco, Calif.

Moves to Larger Quarters

THE Federal Radio Equipment Corporation, that has been located at 11 Broadway, New York City, has moved to new and larger quarters at 6 Murray Street where they have taken over an entire floor for the distribution of Pathfinder Products. Meanwhile at the laboratory, research work continues under the direction of Mr. Verner Hendrickson, (1BKA—also 1XAK) who is an old time wireless amateur. It is the Pathfinder intention, at least whenever possible, to give aid and assistance to the amateur and novice whenever he has need of such for the future development of radio. When these plans are completed announcement will be made.

A New Bradleystat

THE Allen-Bradley Co., 286 Greenfield Avenue, Milwaukee, Wisconsin, have recently placed upon the market a new model of the well known Bradleystat which can be used with all detector and amplifier tubes. The new model, known as the Universal Bradleystat with three terminals, provides extremely wide control in three ranges obtainable by using the proper pair of terminal connections. By means of the new Universal Bradleystat, radio enthusiasts and radio manufacturers can use one rheostat for all tubes and enjoy the same wide range of stepless, noiseless control which the older Bradleystat models provided for a limited number of tubes. The use of scientifically treated discs enables the Allen-Bradley Co. to guarantee the Universal Bradleystat to give perfect filament control for all tubes.

New List of Boys' and Girls' Summer Camps

FOLLOWING is a list of names and addresses of directors of boys' and girls' summer camps, each of whom should be a potential purchaser of radio sets for camp and vacation use. This installment completes the list.

John P. Sprague, 825 Lincoln St., Evanston, Ill.
F. E. Bachhuber, Minocqua, Wis.
Wm. F. Thorpe, Thorpe Acad., Lake Forest, Ill.
G. A. Roger, 700 West Euclid Ave., Detroit, Mich.
Lotta Broadbridge, The Palms Apt., Detroit, Mich.
Homer L. Thomas, 1304 29th St., N. Birmingham, Ala.
H. R. Crook, 5964 N. Hermitage Ave., Chicago, Ill.
A. O. Kelley, Soldan High School, St. Louis, Mo.
A. G. Whitney, Syracuse Univ., Syracuse, N. Y.
Roy S. Claycomb, 14 Clifford St., E. Orange, N. J.
E. A. Chapaan, St. Andrew's College, Toronto, Canada.
A. S. Gregg Clarke, Washington, Conn.
Edward Soles, 308 W. 93d St., New York.
W. L. Wise, Bordentown, N. J.
C. V. P. Young, Cornell Univ., Ithaca, N. Y.
W. L. Childs, New Trier H. S., Kenilworth, Ill.
J. Beach Cragun, Univ. of Chicago, Chicago, Ill.
A. L. Cochrane, Upper Canada College, Toronto, Canada.
Miss Chris Marie Noble, P. O. Box 481, Santa Barbara, Cal.
Miss Sally Joy Leadbetter, P. O. Box 481, Santa Barbara, Calif.
Miss Cecilia C. Kays, 741 New Hampshire Ave., Los Angeles, Calif.
Miss Mollie E. Utz, 158 N. Main St., Salt Lake City, Utah.
Wm. B. McKingert, Berkeley, Calif.
Miss Portia M. Swett, (Winter) Carmel-by-Sea, Colo.
Mrs. Wm. E. Sargent, New Bedford, Mass.
Wm. H. Brown, 311 W. 83d St., New York.
Harry R. Dane, 548 Parkview Ave., Detroit, Mich.
John Linker, 175 E. 79th St., New York.
Elmer Huppert, M. D., 116 W. 59th St., New York.
Martin B. Cohn, 220 W. 98th St., New York.
Maj. Wm. K. Gunn, University School, Cleveland, Ohio.
E. C. Cook, Annandale-on-Hudson, N. Y.
Mr. and Mrs. C. P. Hulbert, 77 Addington Rd., Brookline, Mass.
Lyman B. Tobin, 29 W. 55th St., New York.
W. W. Elder, 39 Draper Terrace, Montclair, N. J.
Leo Bernheim, 880 Southern Boulevard, New York.
D. Ralph Starry, 1309 Denmark Rd., Plainfield, N. J.
S. W. Berry, 311 W. 93d St., New York.
William Zelenko, 850 E. 161st St., New York.
Walter Hullihan, Newark, Del.
Frank F. Hooper, Chattanooga, Tenn.

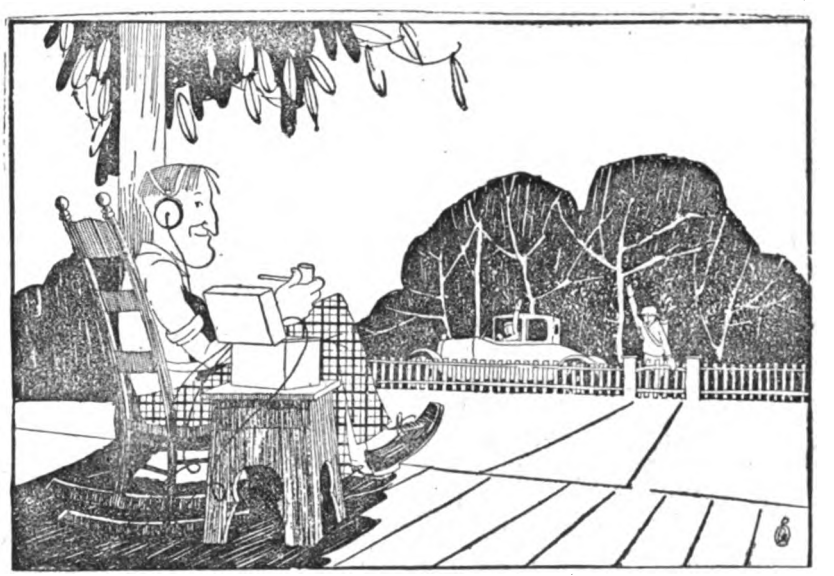
Broadcast Bill's Radiolays

By William E. Douglass

SOME people like to do one thing an' some folks like another, but fer be it from me to judge my neighbor or his brother. A funny place to live in this old world of ours would be if everybody like to do the same as you er me. There's Hezekiah Singletree who plays the clarinet. I'll bet he's practiced twenty years an' can't play nothin' yet. He tunes up every mornin' an' I hear him every night. I' spect in fifty years or so he'll learn to play it right. Ol' Hezekiah's youngest son what went away to school, has got a new game started here he calls "Cow pasture pool." He sez I ought to try fer he knows I'd like it fine; I told him nothin' doin', none of that fool game fer mine. My next door neighbor Silas Brown has bought a brand new bus, it's what he calls a coopie and it don't have room fer us. On Sundays him an' Lil start out,—sometimes they're gone all day, but I don't think I'd like it much to spend my time that way. While he's out burnin' gasoline I'm sitting there at home a takin' life real easy with a headset on my dome. I hear the chapel service from a big broadcastin' station er mebbe sacred concerts from half way across our nation. I can't afford a high priced care to tour the country wide, ner do I care to bat a ball around the mountain side; and as fer homemade music —well I'd rather have the brand that's broadcast some evenin's by that military band. So while these stations send out news an' music superfine, I'm pilin' up my jitneys in that savin's bank of mine, fer I don't have no bills to pay fer oil er gasoline, an tires aren't expenses fer a radio machine. Some people like to do one thing an' some folks like another, so fer be it from me to judge my neighbor er his brother. I'll just keep right on "listnin' in" an' pilin' up my rocks, an' there'll always be tobacco in my old tobacco box.



"I'll just keep right on 'listnin' in.'"

(Copyright, 1923, Westinghouse Electric & Manufacturing Company.)

A Pleased Reader Sends Thanks from the Depths

Editor Radio World:—The article in May 12th Radio World by C. H. Stoup is the best of its kind I've seen since radio "came in." The circuit, of course, is good but his instructions as to tuning deserve to be reprinted and sent to every owner of such a set.

I began two years ago with a regenerative set. We are from 50 to 200 feet below sea level here and the summer heat is 110 to 125 degrees. We have static that is static and dust storms that paralyze our tubes. We have tried everything we ever heard of once. We get good results up to 1,500 miles and in cool weather as far as PWX and WGY. The only way to get results is to follow, word for word, Mr. Stoup's instructions. He certainly knows what he is writing about. This article two years ago would have saved me a lot of grief. Thanking you and Mr. Stoup.

Yours truly,
DR. W. M. CLARK.
Coachella, California.

What Western Fans Like in Broadcasting

By Alice L. Webb

A QUESTIONNAIRE was sent out to all radio fans who had written in to the operator reporting hearing station KFAE, State College of Washington, at Pullman, Wash. Answers were received from 89 of these, of whom 14 were farmers, nine high school set operators. Reports that the signals were unsatisfactory came from two, while 69 said they came in clear and strong, and three that they were too strong. Music was preferred or more of it desired by 17, while 28 wanted more lectures, and 20 reported the present program arrangements satisfactory.

Of those desiring more lectures, a number requested special subjects, particularly radio, both theory and practice. One farmer asked for market and crop reports, another for lectures on history, ancient and modern, and another on language, Spanish or French.

Trouble with tubes and batteries has caused some interruption with recent programs, but that is now rectified ,and distance tests will be made to see how far the broadcast is heard. A Saskatchewan fan won the book offered to the first one 500 miles or more away who reported hearing the book news broadcast.

First Chilean Electric Locomotive

AT the preliminary trial of the first electric locomotive to be run on the Chile State Railways an old woman crossed herself, threw stones at the Baldwin-Westinghouse electric locomotive, and cursed it as the work of the devil. The children who were present threw flowers in the path of the passenger locomotive as it slowly moved down the track. These two demonstrations illustrate how easily the younger generation takes to new ideas. President Alessandri, of Chile, at the official trial several days later, acted as engineer and his American ambassador as assistant as the electric locomotive pulled the first train from Santiago to Tiltil and return. The main artery of the Chilean State Railways is now being electrified. The order for the necessary apparatus, including 33 locomotives and equipment for three substations, totaling $7,000,000, which was awarded in 1921 to the Westinghouse Electric & Manufacturing Co., was the largest foreign order ever received for railway electrification apparatus by any one firm in Europe or America.

New RCA Official in Washington

MR. F. P. GUTHRIE, until recently head of the Radio Division of the Shipping Board, has been appointed district manager for the Radio Corporation of America, with headquarters in Washington, D. C. Mr. Guthrie has followed radio for years and during the war served as a commissioned officer in the Naval Communication Service. It is understood that he will have charge of the corporation's new broadcasting station soon to be opened in Washington, D. C., as well as the commercial work.

Mr. A. H. Morton, who has been in charge of the corporation's commercial station at Washington for some time, has been transferred to New York where he will take up organization duties in that district.

Tubes Replacing Spark Transmitters in Navy

THE Navy communication service both afloat and ashore is rapidly abandoning its spark transmitting sets for new vacuum tube sets, in accordance with recommendations of the Radio Division of the Bureau of Engineering.

Recent experiments indicated that tube sets give excellent results and are far superior to the old sparks. A comparative test between the 100 KW spark set at Arlington, NAA, and a new six KW tube installed there, demonstrated that the new tube will be satisfactory. Naval stations at San Juan, New Orleans, Balboa, San Diego and ships in the Atlantic and Pacific advised that the tube signals were read more easily and had slightly more audibility. The tube set showed harmonics, one of which was on about 350 meters, but with modifications it is hoped that these can be eliminated.

A further successful test between the six KW tube set and the 30 KW arc at NAA was made recently, in which the tube set showed up well. It is probable that arc sets will eventually be discarded, but at present only new stations will get tubes except in replacements.

Two New Radio Manuals

THE E. I. Company, New York City, has just issued two radio manuals under the titles "How to Tune Your Radio Set" and "100 Radio Hook-Ups." Each retails for 25 cents. The author is Maurice L. Muhleman, of the staff of *Radio News*.

In the manual on tuning the author begins by giving the reader a concise outline of just what should be done to tune different types of vacuum tube receiving sets so that he may get the most out of his own outfit. The first step is a thorough understanding of radio waves, and these the author proceeds to explain in a clear and simple manner, assisted by several diagrams.

The manual on hook-ups contains 100 clearly drawn diagrams of circuits, as well as a number of explanatory diagrams, and a schedule of symbols used in the hook-up drawings. Instruments used in the reception of radio telegraph and telephone messages are described briefly.

Amateur Station Heard 11,000 Miles Away

ANNOUNCEMENT was made at Hartford, Conn., recently that an amateur wireless station had succeeded in transmitting signals approximately half way around the world, establishing a new long distance record. A ship operator reports he heard the station operated by E. W. Rouse at Galveston when he was 100 miles southeast of Ceylon in the Indian Ocean, a distance of 11,000 miles.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

Fully Illustrated. Price 75 Cents

N addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

Radio Books to Read on Your Vacation

THERE will be hours of lounging and taking it easy on your vacation that profitably and agreeably may be employed in radio reading. Following is a short list of books which will afford interest and information to the radio enthusiast who is genuinely fond of the art:

"Letters of a Radio-Engineer to His Son," by John Mills, of the Western Electric Company's engineering department. New York, Harcourt, Brace & Co. This is a popular account for real boys of the fundamental principles of radio communication, written by one who knows his subject thoroughly and has the happy knack of imparting his knowledge to others. 265 pp., fully illustrated.

"Radio Reception," by Harry J. Marx, technical editor, The Radio Digest, and Adrian Van Muffling, consulting engineer. New York, G. P. Putnam's Sons. 241 pp., 129 illustrations and diagrams, including many hook-ups. Special reference is made by the authors to practical tuning and to radio and audio-frequency amplification. Every effort has been made to cover only the essentials necessary to convey to the reader a clear conception of the fundamental principles of radio reception.

"Elements of Radio Telephony," by William C. Ballard, Jr., Assistant Professor of Electrical Engineering, Cornell University. New York, The Columbia Print, 1493 Broadway. Over 140 pp., many illustrations. The reader with a technical background will find this book exactly fulfills its purpose, which is to give in an authoritative manner a clear and accurate exposition of radio telephony and its underlying principles.

"Radio," by John R. Irwin. New York, Edward J. Clode. 280 pp., many diagrams and profuse definitions. Lieutenant Irwin begins his book with a preliminary discussion of radio and its history and follows with a complete, concise, practical radio course. The latter part of the book is made up of a series of questions and answers which cover almost every conceiveable radio problem.

"The Book of Radio," by Charles William Taussig, Associate Member, Institute of Radio Engineers. New York, D. Appleton & Co. 447 pp., 181 illustrations. This book reviews the field of present-day radio development in a popular and practical fashion. It is full of information on the construction and manipulation of radio apparatus and discusses the public and private uses to which radio is being put. In a certain degree, the many aspects of radio are here treated as in no other book of its kind.

DeForest Stock Subject of Suit

A SUIT claiming that 86 per cent of the stock of the De Forest Radio Telephone and Telegraph Company had been sold to Edward H. Jewett of Detroit and his associates for $670,000 has been filed in the Supreme Court of New York by Abram C. Wisner of Toronto and Wiley R. Reynolds of Jackson, Mich., against Lee De Forest, Charles Gilbert and Randall M. Keator of New York City. The complaint asks $44,500 on the ground that the defendants controlled the stock and that they had agreed to sell to the plaintiffs for $656,500. Wisner and Reynolds claim that they paid $31,000 on account of the stock, and spent $13,500 interesting other purchasers, and finally induced Mr. Jewett and his friends to buy it. It was said that he had paid $158,000 on account. The plaintiffs seek to recover the money they paid on the stock and their expenses.

Not an adaptation of old methods of current control, but distinctly designed to utilize the great tuning possibilities of the vacuum tube itself.

Ideal Control For All Tubes—

Especially U. V. 199's and all dry cell tubes, permits accurate and superfine adjustment necessary at critical operating point. Regulated at the factory to the ideal "off" point for all tubes obviating the necessity of tampering with any screws or adjustments.

—triple tested

Fil-Ko-Stats are not just fabricated and assembled. Each one is triple tested by an expert—carefully calibrated—then actually operated on a tube.

Reliability and durability backed by the manufacturer's guarantee. There are no disks to break or chip.

What FIL-KO-STAT means to YOU

—stations you never heard before.
—absolutely noiseless operation.
—complete control of electronic flow in the tube.
—the assurance of laboratory tests that you have the best filament control for any make of tube.
—filament control eighteen times greater than with a wire rheostat and many times that of any other so-called filament controls.
—lengthened life for your tubes.

$2.00 at Dealers Everywhere

The filament kontrol of infinite adjustment

FIL-KO-STAT

GUARANTEED by the maker that it will be replaced if broken within one year.

DX Instrument Co. Harrisburg, Pa.

Replaces the rheostat. Occupies little space on panel. No re-drilling necessary. If your dealer has none in stock send his name and your remittance direct to

Westinghouse Has A Satisfactory Year

THE net income of the Westinghouse Electric & Manufacturing Company for the year ending March 31, 1923, was $12,263,485 as shown by the company's annual report. The dividend requirements were $6,033,428, so that over twice this amount was earned and more than six million dollars added to the surplus. Gross sales for the year were $125,000,000, which represents an increase of $25,000,000 over the sales of last year. The cash position of the company is a strong one, the current assets totalling over $106,000,000 and the current liabilities less than $17,000,000.

"The bookings of new business steadily increased during the year," states Guy E. Tripp, Chairman of the Board of Directors, "and the value of unfilled orders at the close of the year was $61,914,237, as compared with $50,740,696 at the close of the previous year. The relations between the company and its employees are satisfactory. Under the company's Insurance and Savings Plan, two-thirds of the employees owned insurance of $500 or more each. The deposits by the employees in the Savings Fund are accumulating at a rate in excess of $100,000 a month, and the total savings to date are in excess of $2,000,000. The savings are invested for the benefit of the employees and are not used in any way in the company's operations."

A plant located at Sharon, near Pittsburgh, Pa., was acquired during the year, and it is planned to concentrate the manufacture of transformers there. Two hundred dwelling houses, located near the company's South Philadelphia Works and formerly the propertv of the Emergency Fleet Corporation, were purchased and are being sold to employees.

Some Hints for Radio Happiness

DON'T expect your loud speaker to give much satisfaction on one tube. It can't be done.

Burn your bulbs up high and cut off about two-thirds of their useful life. They always give better satisfaction if burnt lower.

When you get your set, immediately get a screwdriver, pliers and hammer. Open it up to see what makes the wheels go round and if you can't make it work better than it originally did, take it back and try and collect your money.

Leave your tubes burning all night. It makes a nice, bright light, and doesn't run up the electric bills. Dad will appreciate it.

When you hear about a new tube circuit or piece of apparatus, always knock it, whether you understand it or not. People will then know that you are a newcomer and don't understand radio, and you won't have to disguise yourself.

Radio Definitions—But Different!

Loud speaker—A politician standing on a soap box.

Amplifier—A female scandalmonger.

Detector—A wife's inspecting kiss when you arrive home late.

Oscillator—A woman in a hat shop with Paris creations—and hubby's bank-roll.

Receiver—Friend wife every pay day.

Antenna—Those funny things on a butterfly's head.

Ground—What is left in the coffee pot.

Transformer—Paint, powder and a per-

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Radio Can't Save Sinners, Says Cardinal Dubois

SERMONS broadcast by radio can never convert sinners, Cardinal Dubois, Archbishop of Paris, believes, according to a despatch to the New York *World*. The Cardinal is himself a radio enthusiast and has a receiving station in the Archiepiscopal Palace.

"I find wireless most interesting," he said, "but broadcast sermons cannot be expected to convert any one. Wireless is too dry and cold to have an effect. I have listened to wireless speeches by famous orators and admired their fine phraseology and style, but they left me unmoved.

"Personal magnetism is lacking. A speaker conquers his audience by the eyes, gestures, intonation, personality. If wireless ever transmits simultaneously with the words a living image of the orator, then I may revise my opinion."

Horoscopes Read by Radio from WOR

BELLE BART, astrologist, who has foretold accurately many important events and who is well known to readers of the leading newspapers in this country, will broadcast from WOR, Newark, N. J., every Monday evening at 9:15 p. m. Members of the radio audience desiring to have their horoscopes read can have this done by writing to Belle Bart giving date of birth and initials and three questions they desire answers to.

Effect of Storm on Aerial

As an illustration of how an aerial acts in a storm, a writer in the New York Globe recounts a personal experience at a summer camp where the antenna system was the highest and most conspicuous thing for miles around. Soon after midnight one August morning, a most terrific electrical storm broke out. It was of such violence that for the first time in his radio experience the writer feared that the aerial would be struck. Half a dozen bolts struck trees all around the camp, some as close as four hundred yards, yet the high wires were not even touched! When the storm had abated somewhat the writer ventured forth and carefully touched the lightning arrester and the lead wires; they were positively hot, which shows that the aerial was actually grounding the heavy atmospheric charges.

Radio Develops a Mean One

Smith—Jones has been tormenting me since he left for Cuba. If it's meant for a joke, it's a poor one.

Canford—What's he been doing?

Smith—He's been sending me radio messages stating: "Please find inclosed two cases of Scotch."—New York *Sun*.

Staten Island Residents Form Men's Radio Club of Richmond Borough

A GROUP of radio enthusiasts of Staten Island, N. Y., has recently organized the Men's Radio Club of Richmond Borough. It is an outgrowth of the Castleton Community Council and meets every week in Public School No. 29.

Membership in the club is restricted to residents of Staten Island, 18 years of age or over. A Junior Club, under the supervision of the Men's Club, is in process of formation. Its membership will consist of residents under 18 years of age.

Much interesting work has been laid out for the future in the form of lectures, experimentation and entertainment. "Untechnical Talks on Technical Subjects" have already been given by C. A. Stephen and H. Luyre.

The officers are: President, C. A. Stephen; vice-president, Rudolph Neumann; secretary, F. H. Horenburger; treasurer, H. Luyre; librarian, T. Norton. With all of Richmond County to draw from, a large membership is anticipated.

Important Decision Favors Public Utility Companies

RATES for public service corporations which fail to take into consideration the cost of reproduction at prevailing prices will not be approved by the United States Supreme Court as now constituted. Justice McReynolds delivered such a decision last week in a suit brought by the Southwestern Bell Telephone Company in Missouri.

"It is impossible," the majority opinion of the court said, "to ascertain what will amount to a fair return upon properties devoted to public service without giving consideration to the cost of labor, supplies, etc., at the time the investigation is made."

The Indoor League Likes Radio Sermons

RADIO has invaded the country grocery store. Round-the-stove conferences once devoted to the discussion of national political issues have been suspended in favor of radio broadcast entertainment, addresses and sermons.

A sermon delivered by the Rev. Dr. Philip Frick, pastor of the First Methodist Church in Schenectady, N. Y., was broadcast by WGY, the General Electric Company station. Dr. Frick received the following letter from "Bill" Davenport, of Hillside Farm, Jefferson, New Hampshire:

"You will see by the heading of this letter I am way up in the White Hills, right under Mount Washington. Today, Sunday, I had occasion to go to the store of F. O. Giddon and while there I heard a sermon preached by you which I enjoyed very much. In fact, it is the first one I have heard in 35 years. So you will see I am not much of a churchgoer, and to think you, away off in New York, should be the first one to catch me. The sermon was very distinct and the singing was fine. In our little town we have three churches, but there are quite a few of us old hardshells who rather go to the store and discuss whatever has transpired through the week. I just wish you could have looked in on the bunch while you were preaching. We were all held spellbound. You could have heard a pin drop anywhere in the room. Hope you will not think we are all heathens up here in the mountains. I should be very glad, if you ever came this way, to have you for my guest for a few days. Hope I may be able to hear another one of your sermons."

MAKE YOUR SET A VACATION SET

Reduce STATIC and other interference by using

(Pat. Pending)

The Short Cut Antenna is so arranged that it can be made a part of your set, either by being mounted on the panel or elsewhere. It replaces loops, aerials, electric light plugs, etc. Eliminates lightning dangers. Brings clearer signals and truer tone. Works on all standard vacuum tube sets.

PATENTS—SEND DRAWING OR MODEL FOR EXAMINATION AND OPINION. Booklet free. Watson E. Coleman, Patent Lawyer, 624 F Street, Washington, D. C.

SUPER-SIMPLICITY CIRCUIT—1,000 to 1,500 miles on one tube, one control, 150 to 25,000 meters. No rheostat, storage battery, vario coupler, variometer, 3-coil mounting, variable inductance, taps or radio frequency. Nothing to guess about. Complete hook-up and particulars, $1.00. No checks. Build your own. Save 50% and get better results. RADIO EXPERIMENTAL LABORATORY, Box 194A, Berkeley, Calif.

OLD MONEY WANTED—$2.00 to $500.00 EACH paid for hundreds of Old and Odd Coins. Keep all old money. Send 10 cents for New Illustrated Coin Value Book, 4x6. You may have valuable coins. Get posted. We pay CASH. CLARKE COIN COMPANY, Ave. 83, Le Roy, N. Y.

FREE CATALOGUE. Ebonite panels, 7x12, 50c.; 23 plate variable condensers, $1.25; American No. 200 Tubes, $3.00; Amplifying, $3.75; W. D. 12 Peanut, $5.75; Sockets, 25c. Stewart's Radio Supply Co., 3124 Cherokee St., St. Louis, Mo.

EXCHANGE LETTERS with friends everywhere. Pleasant pastime. Information for stamp. Smith, Box 3125, M. Portland, Ore.

THREE NEW 50 WATT TUBES. Never used. $20 each. W. N. A. B., Bowling Green, Ky.

CRAM'S RADIO BROADCASTING MAP of the UNITED STATES AND CANADA. Scale 100 miles to the inch. In two colors, size 34x28. Printed on high-grade map paper, up-to-the-minute information, indicating all amateur and standard broadcasting stations, with complete index to stations. 35c postpaid. The Columbia Print, 1493 Broadway, New York City.

CASH FOR OLD GOLD, Platinum, Silver, Diamonds, Liberty Bonds, War, Thrift, Unused Postage Stamps, False Teeth, Magneto Points, Jobs, Any Valuables. Mail in today. Cash sent, return mail. Goods returned in ten days if you're not satisfied. OHIO SMELTING CO., 337 Hippodrome Bldg., Cleveland, Ohio.

EDISON Elements for making "B" Batteries, 6c. per pair; tubes 2c. each. Nickel Wire, Insulators, and Cabinets at reasonable prices. TODD ELECTRIC CO., 178 Lafayette St., New York City.

FOR SALE—Receiving set with two stage amplifier. Write for price and description. Fred Rowe, Jr., Hawley, Penna.

EXCHANGE JOLLY, INTERESTING LETTERS through our club. Stamp appreciated. Betty Lee, Inc., 4254 Broadway, New York City

BROADCASTING OUTFIT using five fifty watt tubes to be sacrificed. Everything complete. Make us an offer. Park City Radio Company, Bowling Green, Ky.

FOR SALE—Two Myers Choke Coils, 8 Myers tube receptacles, three Cot-o-Coil Radio Transformers, all for $15.00. F. T. Lesser, 85 Lincoln St., Ridgway, Pa.

HYPNOTISM—Controls self and others. Wants gratified. Ten easy methods, $1.10. "MIND-READING" (any distance)—Wonderful, $1.10. SCIENCE INSTITUTE, RW 1014 Belmont, Chicago.

FOR SALE—Radio Receiver, Navy type, cost $595. Good condition. Dealers invited to call and see. Also 8 genuine "Vario-perm" guaranteed .001 variable condensers. Columbia Print, 1493 Broadway, Room 326, New York City.

RADIO FANS AND PROFESSIONALS—How many of you know the correct CODIFICATION of all characters, punctuations and signs (such as $, %, etc.). We dare say that nine out of ten don't know them correctly! Our instructor who has had 35 years experience, eight years of which were with Uncle Sam as MORSE and RADIO TELEGRAPHER, has just published the first and only CHART known to give fully a true and correct CODIFICATION of ALL characters used in both codes for beginners and veterans alike. Fifty cents (money order preferred) will bring CHART, also much information extremely interesting to BOYS and GIRLS; because, with this information and a little PEP on your part, you can qualify shortly (as scores of our graduates have done) and secure positions paying $1,500 to $3,000 yearly. We are registered with the U. S. C. S. Com. at Washington and can help you. AMERICAN TELEGRAPHIC STUDIO, BOX 793, WORCESTER, MASS.

ELEMENTS OF RADIO TELEPHONY

By WILLIAM C. BALLARD, JR.

Assistant Professor of Electrical Engineering, Cornell University

This is a standard book on radio telephony, the work of a recognized authority.

It is accurate, simple, clear, reliable and strictly up to date.

The man with a technical background who wants to post himself on radio will find this exactly the book for his purpose.

The radio enthusiast will find in it an excellent presentation of fundamental principles and their application.

SENT POSTPAID ON RECEIPT OF PRICE, $1.50, BY

THE COLUMBIA PRINT, 1493 B'way, New York City

Dead Line for Changes in Advertising

Owing to the increase in the sales of Radio World and the fact that the paper has to be sent to press earlier than formerly, no cancellation of or changes in advertisements can be accepted after Wednesday of the week preceding publication.

WOULD YOU LIKE TO RECEIVE RADIO ADVERTISING MATTER?

Are you in the market for radio goods of any kind, either as a consumer, a distributer or a retailer? If so, send us your name and address on a post card and we will see that your name reaches the right people so that you will receive pamphlets, circulars, etc., regarding the goods you want.

ADDRESS SERVICE EDITOR, RADIO WORLD, 1493 BROADWAY, NEW YORK CITY

PATENTS

To the Man with an Idea

I offer a comprehensive, experienced, efficient service for his prompt, legal protection, and the development of his proposition.

Send sketch or model and description, for advice as to cost, search through prior United States patents, etc. Preliminary advice gladly furnished without charge.

My experience and familiarity with various arts frequently enable me to accurately advise clients as to probable patentability before they go to any expense.

Booklet of valuable information, and form for properly disclosing your idea, free on request. Write today.

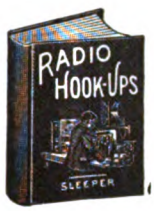
IF YOU ARE INTERESTED IN RADIO YOU NEED THESE BOOKS

Radio Books for the Expert and Amateur

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Radio Hook-Ups

By M. B. SLEEPER

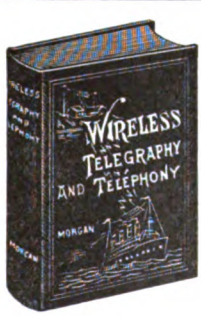
A book that gives you not only clear diagrams for all kinds of telephone and telegraph receiving and transmitting sets, but simple descriptions of each circuit shown and spaces for notes of results obtained.

PRICE 75c.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

There is a peculiar fascination about receiving radio messages from the high-power stations of England, France, Germany, Russia and Italy, as well as those located in the Pacific Ocean and the Oriental countries. Several types of simple receiving sets for this purpose are described, with detectors and amplifiers to accompany them. Suggestions are also given for operating relays and reproducing the signals on a phonograph. Schedules of operating time for high-powered stations are given. In addition, there is some valuable data on home-made wavemeters for testing and experimenting .....PRICE 75c.



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50

Design Data for Radio Transmitters and Receivers

By M. B. SLEEPER

The only book that gives tables and data for designing, receiving and transmitting apparatus so that you need no knowledge of mathematics. It's the first book a beginner buys after he has learned the use of his phone receiver.....PRICE 75c.

Construction of Radiophone and Telegraph Receivers for Beginners

By M. B. SLEEPER

The man who wants to feel the real thrill of accomplishment, and who is not satisfied in the merely making use of what others have done for him, builds his own radio apparatus. Radio men can follow the data in "Radio Phone and Telegraph Receivers" with full confidence, because each piece of apparatus described was first made, tested and found efficient before the final design was accepted. Special receivers, both crystal and audion, are shown in detail. Regenerative circuits as well as audio and radio frequency amplifiers are described with clear photos, diagrams, and working drawings prepared especially for the novice and the man who wants to receive the radio telephone broadcast. A special feature is the phonograph type radio set and the loud speaker. Fully illustrated.....PRICE 75c.

The Radio Experimenter's Handbook

By M. B. SLEEPER

Throughout the preparation of this book, one purpose was kept in mind—Answer the Practical Questions of the "Novice," of the "Beginner," and the more advanced "Student." This book will help in the selection or construction of simple apparatus for the transmission and reception of radio telegraph and telephone signals. In the chapters on radio receivers the simplest crystal, the simple audion, and the regenerative types are described in quite some detail. The question of antennas, both for transmitting and receiving, are taken up. A good many helpful suggestions are given which will be of considerable aid to the experimenter. 16 chapters. Fully illustrated.

PRICE $1.00

The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

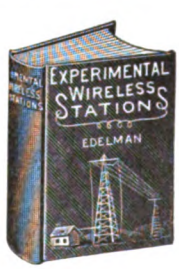
Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

How to Make Commercial Type Radio Apparatus

By M. B. SLEEPER

This book describes in detail many commercial types of spark and vacuum tube telephone transmitting and telegraph and phone receiving equipment of all kinds. The experimenter will be able to get a world of ideas for the design and construction of his next piece of radio equipment from the very clear descriptions and the 98 clearly illustrated figures.....PRICE 75c.



Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations.....PRICE $3.00

THE FADA
ONE-SIXTY

$120.00

"IF WE DON'T GET 'EM ON THE LOUD SPEAKER WE DON'T COUNT 'EM"

The FADA "ONE SIXTY" neutrodyne circuit receiver will consistently bring in broadcasted programs from stations one thousand to fifteen hundred miles distant, with good volume using a loud speaker.

Log records for the evening of May 16th, and under the new broadcasting wave length regulations, listed thirteen stations received with loud speaker intensity. Selectivity between stations very good.

STATION		DIAL 1	DIAL 2	DIAL 3
WDAP	Chicago, Ill.	0	27½	27½
WHN	New York, N. Y.	0	31	29½
WGY	Schenectady, N. Y.	10	35	33
WDAR	Philadelphia, Pa.	12	36	34
WOR	Newark, N. J.	20	40	40
WBZ	Springfield, Mass.	22	24½	23

When Your Set Goes on Strike

SOMETIMES your set for no reason at all just lays down on you and goes out of commission, or stations that pounded in last night are weak and faint tonight. What do you generally do? Go through your set with a fine comb or sit and test out carefully?

What you should do is this: Look at your antenna thoroughly and inspect your ground and lead in. It may be that your antenna has become grounded or that your ground lead is broken or loose. Look at your B battery. They sometimes take a sudden drop in voltage and hence your tubes are not working right. Inspect your tubes. Once in a while the lead nipples on the lugs corrode and form a high resistance path for the current which is equivalent to a bad connection. Examine your phone cords. There may be a break in the tinsel and you need a new cord. In order to test them, turn on your tubes, put on your phones and carefully "feel" the cord, an inch at a time, bending it back and forth. If there is no sudden increase in the strength of the signals the cords are O. K. Never test phones with a battery. Examine all your flexible connections, such as the pig-tail connections on your condensers and couplers.

If all these things seem to be right, carefully inspect the set looking for corroded connections or crossed leads. It stands to reason that if the set worked all right the night before, and no one touched it during the day, that it did not walk around and break itself and that there is only some minor trouble, which can usually be found outside of the cabinet. There is no use to get all worked up and go fishing around inside the cabinet and do more damage than originally caused your trouble.

Germans Radio to Moving Trains

GERMANY recently had a demonstration of wireless telephonic communication between a moving train and ordinary receiving and transmitting stations, according to Consul Richardson at Berlin. Messages were exchanged between the president and officials of the government in Berlin and other officials on a train moving at 30 miles an hour, half-way between Berlin and Hamburg, by means of the "Huth" system. This system is a combination of wireless and wire transmission. The sending apparatus was installed in a compartment on the train and the antenna rigged over the tops of two cars. The line telegraph wires along the track are said to have picked up the messages and transmitted them to Berlin where the line was connected with a receiving set.

Build a Radio Receiver That Your Friends Will Admire

FOR a surprisingly small sum you can now build a real receiver that is surpassed by none in either efficiency or artistic appearance. In a beautifully designed cabinet are a series of instruments that co-ordinate to give an ease of control, long distance reception and elimination of interference which will win the instant approval of the most discriminating. The old reliable regenerative hook-up is used with a wave length range of 150-3000 meters.

A complete set of blueprints has been prepared showing the construction of this receiver in detail. The plans include a distortionless two-step amplifier that matches the receiver in both beauty and efficiency. A bill of material numbered to correspond with the blue prints and wiring diagram eliminates any chance of error and enables anyone without knowledge of radio or mechanics to build this set. Price $2.00 postpaid.

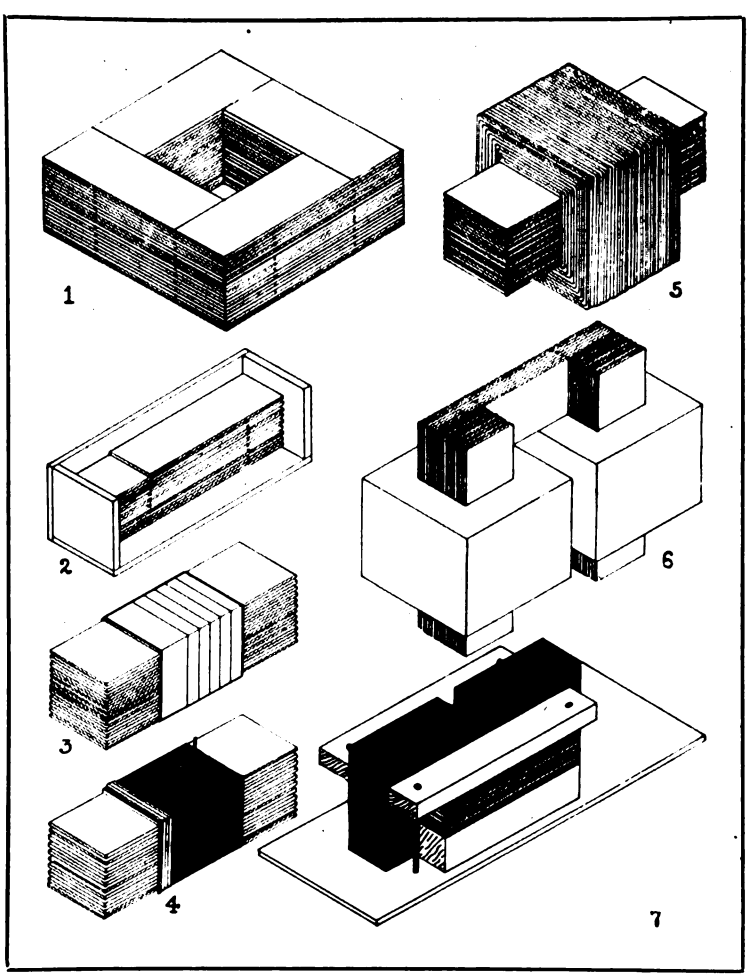
How to Build a Battery Charger for Use with 110 Volts A. C.

By Stuart A. Hendrick 2BJG

ALMOST every one who owns a storage battery wished, at some time or other, that he had a means of charging it just where it stands instead of lugging it off to a battery charging station every time it runs down.

There are numerous charging outfits on the market. The electrolytic or chemical rectifier is very unhandy, unclean and cannot be relied upon to do a good job. It will, in all probability, do more harm than good to your battery. The magnetic type of rectifier is noisy and cannot be relied upon as much as a Tungar, which will be described in this article and, in my opinion, by far the best to use with 110 volts A. C. It is noiseless and is the only one that can be absolutely depended upon to do the charging because it has no moving parts to get out of order and no chemicals to evaporate and give off fumes.

The prices of these rectifiers range from $15 to $30 and quite a part of this sum may be saved by building the rectifier yourself. While some persons have not the patience or facilities for building apparatus of this type others manage to do these things and any one who undertakes to build one of these Tungar rectifiers will find, when he has finished, that he has not only saved considerable money but has a piece of apparatus that is about the handiest thing possible to say nothing of the knowledge gained while obtaining the parts and building the rectifier.



Figs. 1-7. Progressive steps in making the double-wound transformer for use with the battery charger. Each step in the construction is fully explained in the accompanying article.

The Tungar works essentially upon the same principle as the vacuum tube in your receiver, but the bulb is especially built to stand the heavy current that must be passed through it.

The rectifier consists of a transformer which supplies a low voltage for lighting the filament of the special Tungar bulb. The transformer also supplies a higher voltage which is rectified through the bulb and used to charge the storage battery. The transformer will work only when connected to a source of alternating current at a potential of 105 to 115 volts.

There are two sizes of this type of rectifier—the two ampere and the six ampere.

The two ampere size is suitable for changing small batteries of from 10 to 40 ampere hours capacity. This size will be just the one for those who do not discharge their batteries very often and are in no hurry to get them charged again as they will have to leave the battery in charge for quite a few hours in order to get the job done.

The bulb used in this outfit is known as a Tungar or Rectigon bulb and can be obtained from almost any dealer in radio supplies at a cost of $4 for the two ampere bulb.

Obtain one of these bulbs and also get a porcelain base socket to fit it. The socket should be such that when it is fastened to a baseboard the bulb will be in

(Continued on next page)

Digitized by Google

(*Concluded from preceding page*)

an upright position, otherwise the filament will sag when it is heated up and will not operate as it should nor last as long as it ought if used properly. Do not, by any chance, put this bulb in a lighting socket, just because it happens to fit, as it will burn out the bulb and probably blow the house fuses.

The next thing needed is a step-down transformer having a two volt secondary capable of delivering 10 amperes and a 15 volt secondary capable of giving two amperes. The two volt secondary is used for lighting the filament of the rectifier tube while the 15 volt winding furnishes the alternating current to be rectified by the tube and to be used for charging the battery.

As very few will have a transformer on hand to meet these requirements, one will have to be constructed according to the following data:

With any transformer the core is the first consideration and when making a transformer, for amateur use, the only dimensions of importance are the height of the strips or laminations when piled up, as well as the width of them; in other words, the cross-section of the core. The length of the legs or sides depends on the size of the coils to be wound upon them, so they should be made long enough to leave plenty of room for the windings to fit in.

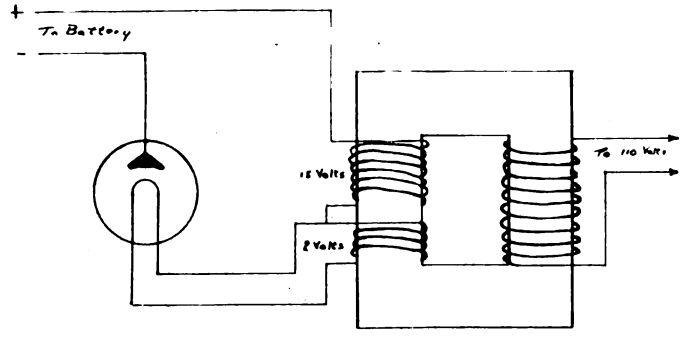


Fig. 8. The way in which to connect the transformer up after making it. Watch your connections on the filament. If the wrong winding is connected you will burn out your tube.

The core used in this outfit was made of strips of silicon steel or transformer iron 1¼ inches wide and piled up to a height of one inch. The sizes were five inches long, which left enough room for the coils.

The core may be obtained from any company that manufactures transformers, for two or three dollars at the most. However, quite a few of you may desire to make the core yourselves.

If silicon steel cannot be obtained, ordinary black stovepope iron may be used and should be about .016 inches in thickness (about 60 thicknesses to the inch).

If this ordinary iron is used in making the core, the cross-section will have to be increased until it is twice as large as that used with the silicon steel because of the lower permeability of the black iron. This will make the core 1¼ inches by two inches instead of 1¼ inches by one inch. The length of the sides will remain the same in either case, that is, five inches wide by five inches long. Any tinsmith will cut it into strips of the proper width for a nominal sum or you may do this yourself if you have a pair of tinsnips and a little patience.

After enough of the pieces have been cut up to the proper size, 1¼ inches by 3¾ inches, they should be piled up as shown in Fig. 1 in order to find out if the corners fit together all right. The next thing to do is to make a wooden frame as shown in Fig. 2 so that the legs upon which the coils are to be wound may be piled up evenly and clamped. As each piece of iron is laid in place it should be given a good coat of shellac. When all of the pieces for one leg have been shellaced and piled up, a piece of wood is put on top of them and clamped down until the whole thing is thoroughly dry after which, when it is taken out of the frame, it will be found to be a solid piece with the shellac holding it together. It should then be taped up as shown in Fig. 3. Two legs should be made up in this manner and when they have been finished the coils should be wound upon them as shown in Figs. 4 and 5. The end of the wire should be fastened as shown in Fig. 4 in order that the winding shall be held securely in place. Plenty of shellac should be applied while winding the coils and when they are finished they should be given an additional coat and placed in a hot oven and thoroughly baked until dry.

The primary coil, or the one that is connected to 110 volts alternating current, is wound upon one of the legs and consists of 605 turns of No. 20 double cotton wire. This winding should be put on evenly and shellaced as shown in Fig. 5. The two secondaries are wound upon the other leg after it has two or three layers of tape on it. The 15 volt winding is put on first and should consist of 85 turns of No. 18 d.c.c. wire. The filament winding is made up of 11 turns of 14 d.c.c. wire wound on top of the 15 volt sceondary.

When these two legs have been wound, shellaced and baked they should be stood on end and the pieces that are to make up the sides should be inserted one at a time until the side is built up as shown in Fig. 6, after which the whole thing should be turned over and the other side put in place in the same manner. The transformer should be given another coat of shellac and place in a box or clamped in a frame of wood or iron to keep the laminations of the core from humming while it is in service. One way of mounting is shown in Fig. 7. The bulb should, in all cases, be exposed to the air so as to keep it cool because it develops quite a bit of heat while in use.

The method of wiring up the outfit is shown in Fig. 8. The wire marked negative goes from the anode of the tube to the negative side of the battery.

The operation of the outfit is as follows: The two volt winding keeps the filament incandescent while the fifteen volt winding supplies the alternating current of which only one-half passes through the bulb which acts as a valve, thereby supplying a pulsating direct current which is suitable for battery charging.

A blue glow will be seen directly above the filament when the rectifier is connected to the battery and is working properly. If the blue glow fails to appear, the end of the fifteen volt winding should be connected to the other side of the filament instead of the side it happens to be on. If then the blue glow fails to appear, the filament should be lighted more brightly by adding a turn or two to the filament winding or by adding more turns to the 15 volt winding to get a higher voltage.

This little rectifier consumes about 50 watts—filament 20 watts, copper and iron losses 20 watts and the charging current takes about 10 or 12 watts. Although the efficiency is not very high the cost of charging is considerably lower than the cost of having the battery charged at a battery station. A six volt 60 ampere hour battery will only cost about 12 to 15 cents to charge, including depreciation of the bulb. With careful handling a bulb will last two or three years. The rectifier may be used with any six volt battery.

With the foregoing data any one ought to be able to construct this rectifier which certainly will be a most useful piece of apparatus.

An Interesting Amateur Station Is 5ZA, Roswell, New Mexico

AN amateur owned and operated station well known in this country and which has the distinction of having been heard in England, Switzerland, Hawaii, Panama, and Porto Rico on an input of only 400 watts is that of Louis Falconi. The station is listed under the call 5ZA and is located at Roswell, New Mexico.

The station, both receiver and transmitter, were made by the owner who describes his apparatus as follows: The transmitter is a combination phone, CW and ICW set with a maximum output of 200 watts for CW and 100 watts when phone is being used. Two five watt speech amplifiers are employed when the set is used as a phone transmitter. Referring to the illustration, the transmitter is located on the right hand side of the table. At the top of the panel is located a thermo-couple radiation meter reading from 0-10. Directly under the meter is the opening for the four tubes. These tubes are mounted directly back of the opening on strips of rubber to prevent all vibration or microphonic noises when the set is in operation. The switch handle under the openings controls a multiple switch for changing the circuits from CW to phone. This is quite a difficult task when it is considered that all the circuits have to be changed as there are speech amplifiers in the phone circuit. The meter at the right center of the panel is for indicating the total plate input on all tubes, while that opposite it is for indicating the plate input on the speech amplifiers. The remaining meter is for indicating the filament current. An anti-capacity switch throws this meter from the power tubes to the speech amplifiers, the power tubes operating best at 10 volts and the speech amplifiers taking 7.5 volts. This switch is located in the center of the panel. The jack at the lower center controls the filaments of the speech amplifiers as well as allowing the microphone circuit to be switched on or off at will. When the microphone jack is plugged in, the filaments of the speech amplifying circuit are automatically switched on. The two handles on either side of this jack control the rheostats one for the primary of the filament transformer and the other the filament of the speech amplifying tubes themselves for fine regulation. As the amplifying tubes use less current than the power tubes, it is necessary to have a separate rheostat for them alone. Two double pole switches control the plate circuit current (1,000 volts D.C.) which is generated from 110 volts A. C. The small panel at the right of the transmitter contains the wave length control and on the panel is a variable inductance and a condenser in series with the antenna. Either of these may be shorted if necessary. The switchboard for the motor-generator control and filament transformers is located directly under this panel, and all connections are made as simple as possible.

The receiving unit is a combination long and short wave set, embodying several unique and original features. It can be used as either a double or single circuit. As the double circuit it uses the regular variometers and couplers. For each circuit there is a separate detector and each can be used with either two steps of audio- or two steps of radio-frequency amplification. In the single circuit set is used a bank wound coupler allowing reception up to 3,000 meters. This can be loaded with honeycomb coils and reception up to 20,000 meters is then possible. The top dial is for the coupling control and under it are the controls for the variable condenser, plate variometer, potentiometers, (two are used—one for control of the plate voltage and one as a stabilizer when the radio frequency amplifiers are in use). The honeycomb coils are used to load the single circuit set. There are six rheostats used, one for each tube (two detectors—one for each circuit). Filament control jacks are used throughout.

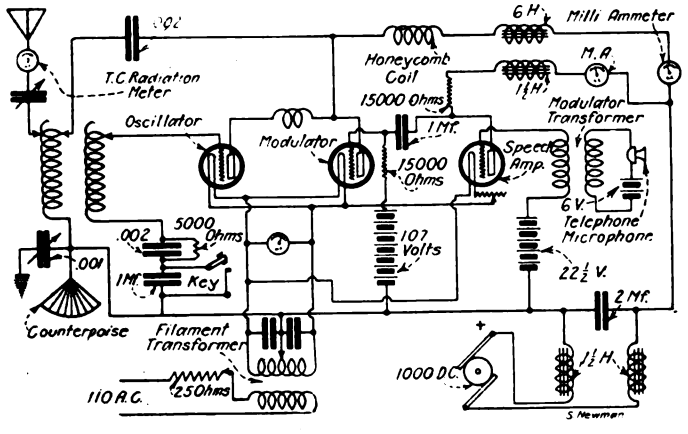

Fig. 1. Circuit diagram of the extremely efficient transmitter used at 5ZA and described in the accompanying article.

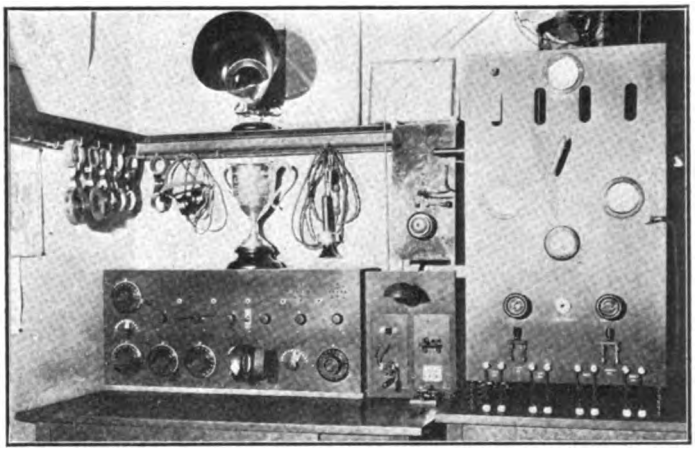

Fig. 2. Transmitter (right) and receiver (left) of Station 5ZA.

In the center of the panel is an anti-capacity switch which throws all the circuits from long wave single circuit to short wave regenerative double circuit. This change involves a transfer of radio-frequency detector and audio-frequency circuits as well as the antenna and ground connections. Capacity effects are nil in this receiver as the entire receiver is screened and grounded. A very valuable feature of the receiver is that in transmitting, by throwing the circuits to the long wave circuit side and tuning to a harmonic of the transmitted wave, a check may be had on the character of the tone and of the transmission.

Using this receiver amateurs in every district are heard nightly. Using the long wave single circuit UFT, POZ, NPO are heard constantly and broadcasters all over the United States, Canada and Cuba are heard.

A point of interest to amateurs is the Hoover cup, awarded during the contest in 1921, shown in the background of the illustration. This station took second place in 1922.

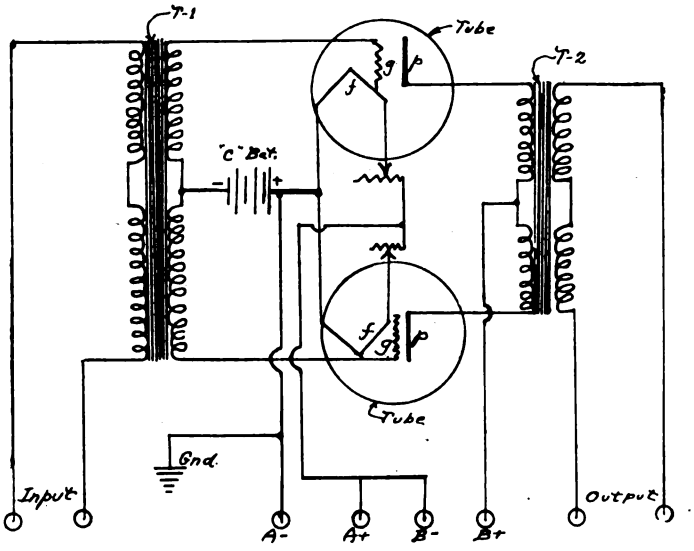
How to Make a Super Amplifier

By C. White, Consulting Engineer

WITH the coming of the warm weather many new radio troubles present themselves for our solution. The increase in the amount of atmospherics and the decrease in radio transmission efficiency makes it very necessary to resort to various types of amplification to get the same amount of volume that we have been accustomed to get in the winter months. The popularity of the many styles of loud speakers again emphasizes the fact that we are not going to cover our ears with phones all the time. Who can conveniently conceive a dance with phone receivers on our ears? Still this summer the popularity of radio music for dances in summer camps and hotels is certainly sure to come and means must be taken to see that ample amplification is available in order greatly to augment the weakened signals.



Schematic diagram for the construction of a power amplifier using two transformers of the push-pull type. This will give exceptionally loud amplification with little distortion.
